# INDEX TO VOLUME I FOR 1925.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, X Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

## A.

Abattoirs, public, number of (parliamentary note), 753  
 Abdomen, acute surgical lesions of, simulated by epidemic encephalitis (G. H. Stevenson), 68 (O)  
 Abdominal aneurysm, rupture of, simulating acute intestinal obstruction (H. Jaffé), 1173  
 Abdominal emergencies in children (M. Fitzmaurice Kelly), 927  
 Abdominal wall, rupture of, with protrusion of uninjured intestine (R. W. P. Hosford), 305  
 Abell, J. J.: Tests for hepatic efficiency, 272  
 Abell, L.: Osteonitis in phalanx of finger and metacarpal of thumb, 267—Osteomyelitis, 267—Osteogenesis imperfecta, 257—Osteo-arthritis of the sterno-clavicular joints and hip, 267—Familial exostosis of the upper dorsal vertebrae, 885—Bilateral osteomyelitis, 885  
 Abercrombie, Lord: Beguest to Edinburgh University to found a chair in prehistoric

516  
 ABRAHAM, Adolphe: Group medicine in practice, 1173  
 ABRAHAMSON, Leonard: Fröhlich's syndrome, 117—Diabetes insipidus with symptoms of hypopituitarism, 118—Clinical blood cultures, 118—Empyema, 458  
 ABRAHAM: A Preliminary Communication concerning the "Electronic Reactions" of Abraham, with special reference to the "Emanometer"

in 25-  
 paratus  
 to the

Royal Society of Medicine by a committee of which Sir Thomas Horder was chairman, 179  
 —New Zealand practitioner struck off the Register, 1023

Abscess, brain, of aural origin (Courtenay Yorke), 354 (O)

Abscess, brain, simulating dementia paralytica (S. Grossman), 553 (O)

Abscess, cerebellar (John Livingstone), 1172

Abscess, encysted psoas, operation, recovery (Griffith Evans), 112

Abscess, lumbar (parliamentary note), 995

Abscess, retropharyngeal; secondary haemorrhage; ligature of common carotid; recovery (P. K. Liang, C. H. Lee, and P. T. Liang), 967

Abscesses, multiple, emboembolic as an etiological factor in (Olive J. H. Sharp and Henry Morrison), 225 (O)

Abb, Isaac A. (and Johannes REUMANN, editors), *Pediatrics*, rev., 101

Académie de Médecine of Paris: Annual meeting, 134—Prizes of, 134—Bacteriolytic action of river waters, 479—Proposed system of general insurance, 628—Antisiphilitic vaccination, 628. See also France

ACADEMY, ROYAL, OF MEDICINE IN IRELAND: Carcinoma of the rectum complicated by pregnancy, 826

Section of *Anatomy and Physiology*.—Congenital cystic kidney, 368—Nutrient foramina

aboutism, 928 — Otorrhoea, 1082 — Osteomalacia, 1082  
 Section of F  
 small intestine  
 isomorphous,  
 kidney, 164—Cy  
 65—

Deep-ray therapy, 458—Immunization against tuberculosis, 741—Manganese and antibody production, 1129

Section of *State Medicine*.—Infantile mortality, 605

An Address  
ON

**IODINE IN EXOPHTHALMIC GOITRE.**

DELIVERED BEFORE THE NORWICH MEDICO-CHIRURGICAL  
SOCIETY, OCTOBER 14TH, 1924,

BY

FRANCIS R. FRASER, M.D., F.R.C.P.E.,

DIRECTOR, MEDICAL PROFESSORIAL UNIT, ST. BARTHOLOMEW'S HOSPITAL.

*Introduction.*

A RELATIONSHIP between endemic goitre and iodine appears to have been recognized for many years. Coindet<sup>1</sup> in 1820 reported that by the administration of iodine goitres could be diminished in size. Chatin,<sup>2</sup> a French chemist, wrote extensively in 1850 and the years following, reporting his investigations on the amounts of iodine in air and soil and water, and he drew attention to the high incidence of endemic goitre and cretinism in localities where the amount of iodine was low. He further maintained that endemic goitre could be prevented by increased ingestion of iodine.

Following Chatin's work, iodine was used extensively in the treatment of goitre until evidence accumulated to show that, following iodine treatment of endemic goitre, the subjects frequently developed tachycardia, tremor, loss of weight, etc. Krehl,<sup>3</sup> Kocher,<sup>4</sup> and others, pointed out that iodine treatment in simple goitre could bring about a condition of exophthalmic goitre, or Graves's disease, and warned against its use. Probably for this reason its employment became much less general. In recent years it has been revived, largely as the result of the work of Marine.

In 1896 Baumann,<sup>5</sup> by demonstrating the presence of iodine in the normal thyroid gland, initiated a series of valuable investigations. The normal thyroid tissue, when dried, contains from 0.1 to 0.6 per cent. of iodine, and is eight to ten times richer in iodine than any other tissue in the body. Magnus-Lervy,<sup>6</sup> in 1895, showed that thyroid tissue has a powerful effect on heat production in the body, and Kendall<sup>7</sup> in 1914 isolated in crystalline form the substance thyroxine, which has the same action on heat production as the whole gland substance, and which contains 65 per cent. of iodine. Marine and Lenhart<sup>8</sup> showed that when the iodine content of human glands falls below 0.1 per cent. the gland shows changes of hypertrophy and hyperplasia, and that in glands showing a high degree of hyperplasia iodine is found only in traces or is absent. If the gland reverts to the resting condition—that is, to the colloid type of goitre—the iodine content rises. If the gland tissue contains over 0.1 per cent. of iodine histological examination will show no hypertrophic changes. Marino and Lenhart further showed that, after a partial thyroidectomy in experimental animals, hyperplasia of the remainder did not occur unless its iodine content fell below 0.1 per cent., but that if as much as three-fourths of a gland were removed and iodine administered to the animal, the hyperplasia that would otherwise have occurred could be prevented.

On the basis of these researches the prevention of endemic goitre by means of the administration of minute quantities of iodine is now practised in many parts of the world.

Exact knowledge of the cause of goitre is, however, still small. Whatever the cause, it would appear that iodine deficiency is one step in the process. It seems probable from the work of Marine, and of McCarrison<sup>9</sup> in India, that this deficiency may result (1) from a lowered intake of iodine, or (2) from a normal intake and a raised demand for iodine on the part of the body. Their researches point to several ways in which this increased need for iodine may be brought about. At certain periods in life, such as puberty, pregnancy, lactation, there seems to be an increased need of iodine. Faulty dieting, and especially excess of fat in the diet, has been shown to lead to hypertrophy and hyperplasia, and the addition of iodine can prevent this response of the gland to excess of fats. McCarrison has postulated a fat-iodine-thyroid balance on the results of these experiments. Pollution of food and of water has also been shown to produce hypertrophy and hyperplasia, and that this is preventable by the ingestion of iodine. All these researches refer to the simple hypertrophy and hyperplasia that is seen in endemic goitre and sporadic goitre, or to experimental conditions in animals that show the same histological changes as are seen in these goitrous conditions in man. These conditions in the individual may lead to the subsequent development of myxoedema, and the offspring of goitrous females are frequently cretins. In myxoedema and cretinism there is indisputably a lack or absence of the iodine-containing thyroid substance, and Marine has pointed out that endemic goitre and sporadic goitre, as well as myxoedema and cretinism, must be regarded as deficiency diseases, and that in all of them there is a deficiency of iodine. The goitre is the result of a response on the part of the thyroid gland to this deficiency. In myxoedema and cretinism the gland is unable to respond because of atrophy or because of congenital deficiency.

In patients with exophthalmic goitre—which in many respects appears to be hyperthyroidism—symptoms of myxoedema frequently develop, and every gradation may be found between these two apparently opposed states. In exophthalmic goitre the thyroid gland shows an exaggerated and irregular hyperplasia, and the iodine content is extremely low.

In 1920 McCarrison<sup>10</sup> reported that the hyperplastic thyroid glands that resulted in pigeons fed on an excess of butter without iodine showed on histological examination an irregular type of hyperplasia with vesicular budding similar to the picture seen in the glands of human cases of Graves's disease. In 1921 E. and M. Mellanby<sup>11</sup> reported that, in the course of their experimental work on rickets and on defective teeth in dogs, they found in the animals fed on an excess of butter a hyperplasia of the thyroid gland histologically resembling that seen in exophthalmic goitre, but that in the animals fed on an excess of fat in the form of cod-liver oil this hyperplasia did not result. They suggested that the high iodine content of the cod-liver oil was responsible for the difference.

These facts suggested that in exophthalmic goitre also an iodine deficiency might be present, and that the administration of iodine might have some therapeutic value in cases of this disease. Iodine therapy has been tried frequently in exophthalmic goitre, but an increased severity in the symptoms may result unless the dose is carefully regulated. This fact, and the frequently recorded examples of exophthalmic goitre symptoms developing during the treatment

of simple goitre with iodine, have led most authorities to issue strong warnings against its use if any symptoms of Graves's disease are present.

Such was the knowledge of iodine in relation to exophthalmic goitre a few years ago, when we commenced to study the therapeutic effect of iodine in cases of exophthalmic goitre. As so often happens, workers in other countries commenced similar studies at about the same time, notably in the Mayo Clinic, and after the results of our observations in the wards of the Medical Unit at St. Bartholomew's Hospital have been discussed reference will be made to several publications that have appeared in the last few months.

#### Preparation of Iodine Employed.

Throughout these observations the iodine preparation used has been the 10 per cent. tincture of the French *Codex*, in which the iodine is dissolved in 95 per cent. alcohol without the addition of any iodo. This preparation was selected because it contained no combined iodine. On adding it to milk the iodine is precipitated, but on stirring it is efficiently suspended, and the mixture is quite agreeable to take. It is probable that it is immaterial in what form the iodine is administered, so long as it is not in an inactive organic combination.

#### Results of Iodine Treatment.

Since March, 1921, we have been able to observe the action of iodine on 24 cases of exophthalmic goitre in the wards of the hospital. In addition to these cases there have been a small number who have received treatment as out-patients only, but in whom the conditions were not sufficiently under control to allow of deductions as to the effect of the treatment. In the following 8 of the 24 cases the results were sufficiently clear to justify detailed accounts of them in illustration of the action of the drug in exophthalmic goitre.

##### CASE I (Chart 1).

A woman, aged 27, who had noticed palpitation and shortness of breath in the beginning of 1922. In March they were sufficiently distressing to interfere with her work in the house, and swelling of the neck was noted. She was admitted on June 20th, 1922, as she had developed auricular fibrillation. This had disappeared by the next morning, but the heart rate was 120. Tremors were pronounced; exophthalmos was not pronounced, but von Graefe's and Joffroy's signs were present. The thyroid gland was enlarged, soft, and pulsating. There was a perforation of the right ear-drum septic. By July 3rd, when her basal metabolic rate was +48 per cent., the heart rate had settled to between 80 and 90 and the tremors were less, but she had lost weight steadily. The ear condition was being treated by syringing, and the general condition

CHART 1.

was but little improved when, on July 21st, tonsillectomy was performed. By August 8th considerable improvement had taken place, the basal metabolic rate being +28 per cent. and the heart rate 82. Iodine was commenced in doses of  $\pi$  xv daily, of the metabolic rate was +10 per cent. and by August 11th the basal metabolic rate was +3.5 per cent. and the heart rate 76. On August 15th the basal metabolic rate was +3.5 per cent. and the heart rate 68, while she had commenced to gain weight. She was discharged from hospital, but in a few months' time was as bad as on admission. While an out-patient, although she felt better taking iodine, it had no obvious effect, and when the arrhythmia commenced to fibrillate again she was readmitted for surgical treatment.

##### CASE II (Chart 2).

A woman, aged 20, who for six months before admission in May, 1922, had noticed shortness of breath, swelling of the neck, and nervousness. The heart rate was 110 to 120 on admission. The thyroid gland was symmetrically

enlarged, soft, elastic, and pulsating. All the classical eye signs of exophthalmic goitre were present. With rest in bed the heart rate fell to 94, but she continued to lose weight, and the basal metabolic rate, which shortly after admission was +54 per cent., had by June 22nd fallen to +47 per cent. only. Commencing June 22nd,  $\pi$  xv of the iodine solution were given daily, and this was increased to  $\pi$  xxx on June 29th. By July 10th the heart rate was

CHART 2.

76, the basal metabolic rate was not increased above the normal level, and the body weight was steadily increasing. On discharge from hospital the condition soon relapsed, and by October the greatly increased hardness of the thyroid gland caused the administration of iodine to be stopped. It was started again later at a smaller dose, as the patient thought she was better when taking it, but it had no noticeable effect, and she was readmitted in February, 1923, with a heart rate of 130, and basal metabolic rate of +68 per cent. With rest in bed the heart rate dropped to 110 to 120, and the basal metabolic rate to +56 per cent. Iodine was started, in doses of  $\pi$  ix of the solution daily, on February 15th. On February 24th the heart rate was 96, and the basal metabolic rate +25 per cent., and a few days later she was transferred to the surgical side for thyroidectomy.

##### CASE III (Chart 3).

A married woman, aged 49, who was said to have had exophthalmic goitre off and on since the age of 33. There had been a recent increase of palpitations, sweating, headache, and nervousness, and she was admitted in November, 1922, with auricular fibrillation, which disappeared, however, after a few hours' rest in bed. The following day the heart rate was 110 to 120. The thyroid gland was enlarged throughout, but the left lobe was larger than the right, and it was firm and elastic and not markedly vascular. Flushing and sweating were marked, and there was a fine generalized tremor. The eyes were somewhat shining and glistening, but no definite eye signs were present. With rest in bed for three weeks, the initial basal metabolic rate of +41 per cent. had fallen to +32 per cent., the heart rate was not altered, and the body weight had fallen steadily. Iodine was commenced on

CHART 3.

December 19th, in doses of  $\pi$  ix daily, and by January 15th, 1923, the basal metabolic rate was +3 per cent., the heart rate 94, and she had gained 16 lb. in weight. Her general condition was greatly improved, and she was discharged. After a few months at home her condition was as bad as on admission, and although she always felt better when taking iodine, it had no obvious effect, and partial thyroidectomy was performed. Some doubt existed as to the diagnosis of exophthalmic goitre. While administration of iodine for several months, even in doses as small as  $\pi$  iij daily, caused the gland to become very hard, and increased the excitability of the patient and the rate of the heart.

##### CASE IV (Chart 4).

A man, aged 40, who for two years had noticed nervousness, palpitations, and weakness, and for six months before admission had noticed swelling of the neck. He had lost 2 st. in a year, and had frequent attacks of sore throat. On admission to hospital in April,

1923, the heart rate was 100 to 120, and the basal metabolic rate was +75 per cent. There was slight exophthalmos, the palpebral fissures were wide, and the conjunctivae glistening. The thyroid gland showed a uniform enlargement, it was soft and pulsating, and there was a loud bruit audible over it. A fine tremor was present. The tonsils were large and showed points of exudate. Tonsillectomy was performed on May 8th, and on May 16th the

FIGURE 4.

basal metabolic rate was +46 per cent., the heart rate was as on admission, and he had lost weight steadily. Iodine  $\pi$  vj daily was started on May 16th, and later increased to  $\pi$  lx and then to  $\pi$  xli, and he commenced to improve in a striking manner. By June 10th the heart rate was 91, and he had gained a stone in weight. On May 25th the basal metabolic rate was +22 per cent. Unfortunately no further estimations were made. Partial thyroidectomy was performed on June 21st.

## CASE V.

A woman, aged 45, who complained of weakness and tremors following an attack of tonsillitis in November, 1921. In May, 1922, the swelling in the neck was noticed, and in December, 1922, she was told her eyes had become prominent. On admission, on February 23rd, 1923, the heart rate was 120, and the basal metabolic rate +61 per cent. The thyroid gland was uniformly enlarged, soft, and pulsating, and a loud bruit was heard over it. Exophthalmos and von Graefe's and Stellwag's signs were present. The patient's voice was husky, there was a fine generalized tremor of the muscles. Considerable improvement resulted from rest in bed, and on March 7th, when iodine was commenced, the heart rate averaged 101, and the basal metabolic rate was between +30 per cent. and +40 per cent. Two weeks later the basal metabolic rate was +16 per cent., the heart rate 81, and the body weight rose to +39 per cent., the heart rate to 116, and the weight ceased to increase; after recommencing it the basal metabolic rate rose to +39 per cent., the heart rate to 116, and the weight dropped again to +16 per cent. At the end of two weeks, the heart rate to 90, and she was again gaining weight. In spite of continuing the administration of iodine, the improvement was not maintained. The onset of an attack of tonsillitis may have been responsible for this, or a less strict condition of rest, or both.

## CASE VI.

A married woman, aged 41, who had had a history of exophthalmos for five years, palpitations, dizziness, and digestive troubles for more than one year, and a vague history of swelling in the neck from time to time. On admission, in November, 1923, general nervousness and excitability were marked. The heart rate was 112, and the basal metabolic rate +60 per cent. to +70 per cent. The thyroid gland was soft, symmetrically enlarged, and a bruit was audible over it. Besides exophthalmos, all the classical eye signs were present, but there was no tremor. With rest in bed the heart rate dropped to 98, but there had been little improvement otherwise when iodine was started in doses of  $\pi$  vj daily on December 11th. On December 21st the basal metabolic rate was +23 per cent., and the heart rate had been as low as 86. The patient became very excited during the Christmas festivities, and this was held to account for the fact that for a period of three or four weeks the condition relapsed. Towards the end of January, although the dose of iodine had been reduced to  $\pi$  iv, the heart rate and the basal metabolic rate were again falling, but not so satisfactorily as in December. The body weight had, however, increased continuously since the commencement of the iodine treatment.

## CASE VII.

A married woman, aged 43, who had noticed prominence of the eyes and shortness of breath on exertion for eighteen months, disturbed sleep for eight months, and severe weakness and tremor for four months. She was admitted in December, 1923, with a heart rate of 100, and basal metabolic rate of +46 per cent. Exophthalmos and all the classical eye signs were present. The skin was moist, and the conjunctivae glistening. Tremor was not marked. The enlargement of the thyroid gland was slight but symmetrical, and no bruit or thrill was noted. Under iodine,  $\pi$  vj daily, the basal metabolic rate fell to +22 per cent., and the heart rate to 82, but the improvement was not maintained and no gain in weight resulted.

In this case there were serious family troubles owing to the patient's absence from home, and it was soon seen that

no further benefit would be derived from hospital treatment. The improvement that results from iodine seems to have a feeble hold, for in this case worries, in Case vi excitability, in Case v tonsillitis, and in Cases i, ii, and iii less strict conditions of rest, all caused it to disappear to a greater or less extent. The following case is given in detail, not so much because it illustrates a typical action of iodine, but because the effect of the iodine was so striking, though unusual.

## CASE VIII.

A woman, aged 31, who had had increasing symptoms of exophthalmic goitre for one year, but who was found after admission to have a staphylococcal septicæmia in addition. She was given iodine for four days, and received  $\pi$  lxxx in all. At the end of the four days the heart rate, which had been 116, had fallen to 62, and after continuing at that level for two more days was again rapidly to 100. No other cause for the fall in rate could be discovered, and no disturbance of cardiac mechanism was suspected, the heart's action being regular throughout the fall and subsequent rise of rate.

This case appears worth recording if only to show that iodine is capable of profoundly influencing certain functions of the organism in disease. Of the remaining 16 cases, in 9 there was evidence of beneficial action similar to that seen in the foregoing cases. In these the observations on the basal metabolic rate were not so complete, or other factors disturbed the action, so that they do not present such a clear picture. In others, again, a sufficient control period without iodine was not present. Among these 9 cases are examples illustrating further some of the points already brought out. It was frequently seen that on the patient being allowed up, and more particularly on leaving hospital, the condition relapsed in spite of continued iodine administration. On the other hand, such patients are almost unanimous in stating that they feel better when on iodine. In a man aged 40 the subjective distress and nervousness improved strikingly, and the heart rate was slowed, but there was little or no effect on the basal metabolic rate. In a woman aged 44 the improvement in the general condition and basal metabolic rate was striking, but persistent auricular fibrillation set in, and the picture of exophthalmic goitre became overshadowed by that of circulatory insufficiency. Two cases in whom constipation had been troublesome to manage developed a desirable looseness of the bowels after commencing iodine, and the ward sister states that in other cases a similar action was noticeable, though to a less extent.

In 5 cases no beneficial action could be noted, but in 3 of them coincident infections may account for this. In one, septic teeth and chronic appendicitis, in another tonsillitis, and in a third bronchopneumonia, may have prevented the evidence of iodine action being seen. In none of the five was any harmful effect discoverable. In 2 cases undesirable effects were prominent. In one, a woman aged 20, tonsillectomy and rest brought about considerable improvement, but the commencement of iodine increased the severity of the symptoms—the thyroid gland became extremely hard, and troublesome diarrhoea appeared. The basal metabolic rate had before treatment with iodine been +20 per cent., and after the diarrhoea set in it rose to +40 per cent. The condition subsided somewhat on stopping the administration of the iodine, and partial thyroidectomy was performed. In the other case, that of a woman aged 27, considerable improvement occurred in the ward after tonsillectomy, and further improvement was seen on commencing iodine in doses of  $\pi$  xl, and later of  $\pi$  lx and  $\pi$  clxxx; but on leaving hospital on this last dose the thyroid gland became hard and appeared increased in size, and distressing palpitations appeared.

## Regulation of Dosage.

It will be seen that in those two cases in which harm resulted much larger doses than those usually given were employed. They were in the earlier days of our observation, and because of the very promising results obtained with the smaller doses, the larger doses were the result of an attempt to obtain even better results. As a result of experience we soon learnt that doses of  $\pi$  ix and  $\pi$  xv daily gave as good results as could be obtained with larger doses. If, however, such doses were continued for long, after a

varying number of weeks the thyroid gland would become gradually harder, and distressing symptoms of palpitations, pressure in the neck, choking sensation, and occasionally increased exophthalmos and tachycardia, would develop. After obtaining a decided benefit on daily doses of  $m\ ix$  or  $m\ xv$ , and no further improvement occurring, the dose is reduced to  $m\ vj$  or  $m\ iij$ , and the patient can continue on such doses almost indefinitely. In each case repeated examination is necessary to ascertain the optimum dose to maintain the improved condition. On the appearance of a rise in heart rate, or of the gland becoming harder, all iodine is omitted for one or two weeks and then recommenced on a lower dose.

#### Therapeutic Value.

In spite of such careful regulation of dosage, the ultimate results have not been as good as might be expected, for, as seen in the cases detailed, worry, excitement, and infections can undo all the benefit derived from the iodine. I think, further, that iodine cannot withstand the consequences that the daily contact with the world, either at work or at home, has on patients with exophthalmic goitre, and that so far it is of limited value in the medical treatment of the condition. If the patient can afford to lead a sheltered life it is a valuable addition to the other means at our disposal for managing a condition that in the majority of cases gradually subsides in time. But its very striking action has a much greater value than this, if it is combined with surgical treatment. The great majority of cases of exophthalmic goitre cannot afford to lead a sheltered life, and for them the only treatment that holds out the hope of a recovery sufficient to allow of successful competition in the struggle for a living wage is by means of surgery. Iodine treatment can so improve the patient's condition, even if temporarily, that surgical treatment by partial thyroidectomy becomes much simpler and much safer.

#### DISCUSSION.

In the last few months several reports on the action of iodine in exophthalmic goitre have been published. Plummer and Boothby,<sup>12</sup> reporting from the Mayo Clinic, base their deductions on their experiences with 600 cases in all, of which 43 were studied carefully. They administered the iodine in the form of Lugol's solution, which contains 5 per cent. iodine in 10 per cent. potassium iodide. In their summary they state that "it seems probable that approximately two-thirds of the patients with exophthalmic goitre will be greatly benefited, one-fourth will be slightly benefited, the remainder—or about one patient in twenty—will not be benefited." They consider that there is practically no probability of iodine doing any harm. In their recorded observations there is no mention of any attempt to use the larger doses which we employed at the outset, and which I think are capable of doing harm, and since their cases appear to have been in course of preparation for surgical treatment it is unlikely that they ever observed the action of even small doses of iodine over a prolonged period. Our results point strongly to the possibilities of harm even with such small doses as  $m\ vj$  of the 10 per cent. tincture, if continued for several months or weeks. Plummer and Boothby employ doses of ten drops of Lugol's solution daily for the average case, and may in urgent cases give as much as thirty drops for a few days only.

Mason,<sup>13</sup> reporting from Montreal, also uses Lugol's solution, and his experience is the same as that of Plummer and Boothby. He emphasizes the immediate relapse of the clinical condition on stopping iodine.

Jagic and Spengler<sup>14</sup> used a 5 per cent. solution of sodium iodide in the treatment of various types of goitre, and they report that, in 5 cases with symptoms of exophthalmic goitre, 2 were improved, 2 others relapsed after a preliminary improvement, and the fifth became worse. They advocate the use of eight drops of the 5 per cent. solution of sodium iodide, three times a day, in cases of goitre with thyrotoxic symptoms.

Wahlberg<sup>15</sup> used a 5 per cent. solution of potassium iodide in maximum doses of fifteen drops a day. In 2 cases out of 8 he found that after a preliminary improvement the disease became worse. The ultimate results on the

whole were not satisfactory, and he believes that the problem is largely one of dosage, and that the initial benefit is destroyed by a cumulative action of the iodine.

Starr, Walcott, Segall, and Means<sup>16</sup> followed the lines reported by Plummer and Boothby, and, using Lugol's solution in the same doses, confirmed their results. They also noted the temporary character of the improvement, and use the term "iodine remission" to describe the benefits obtained, and also noted that in some cases no effect is observable.

Since the cause of exophthalmic goitre is at present unknown, it is not easy to decide on the meaning of this action of iodine. The recent experimental work of Marine<sup>17</sup> on the result of damage to the cortex of the adrenal bodies is of interest in this connexion. He found that such damage in rabbits causes an increased heat production—that is, a rise of basal metabolic rate—and a loss of iodine in the thyroid gland. If the thyroid had been removed previously, this rise of heat production did not occur. Clinically these animals, in whom the adrenal cortex was damaged, showed features resembling those seen in exophthalmic goitre—namely, asthenia, exhaustion, myocardial damage, and loss of nutrition. These results appear to support the prevalent ideas that in exophthalmic goitre other organs of internal secretion besides the thyroid are essentially, and possibly primarily, involved.

It is tempting to try to bring exophthalmic goitre into line with the simpler goitres as an iodine deficiency disease, and to account for the different types of goitre by differences in the response of the thyroid and of the body generally to iodine deficiency. The results of iodine treatment in exophthalmic goitre, however, justify merely the view that in this disease there is an iodine deficiency relative to the needs of the body. It may be that the primary disturbance, whatever that may be, involves the thyroid gland in addition to other organs, and that the thyroid is stimulated to overactivity. This overactivity, by greatly increasing the need for iodine, would then result in a relative iodine deficiency. On this hypothesis, the administration of iodine would be of value in the treatment of what is merely a symptom, while it would have little if any effect in altering the course of the disease, and the administration of large doses would result in harmful effects, just as in the treatment of simple goitre.

#### SUMMARY.

1. The effect of iodine administration has been studied in twenty-four cases of exophthalmic goitre.
2. Iodine can bring about a lowering of basal metabolic rate, and of heart rate, and an increase of body weight, with a striking improvement in the general condition of the patient.
3. The improvement obtained with iodine does not as a rule persist.
4. The optimum dose at the commencement of the treatment appears to be about  $m\ xv$  of a 10 per cent. solution in alcohol, but this dosage cannot as a rule be maintained more than a few days or weeks. If the administration is stopped the condition immediately relapses. For prolonged treatment the dose should be lowered as soon as the initial improvement has taken place, and the administration continued with doses of  $m\ iij$  to  $m\ vj$  daily. The dosage must be carefully regulated according to the condition of the patient.
5. Increasing hardness of the thyroid gland is an indication for a smaller dosage.
6. The condition of the patient may be made worse, instead of better, if too large a dosage is employed.

'CHRONIC MASTITIS' AS A TERM:  
ITS FALLACY AND THE DANGER OF  
ITS CLINICAL SIGNS.\*

BY

SIR G. LENTHAL CHEATLE, K.C.B., C.V.O., F.R.C.S.,  
SURGEON AND LECTURER IN SURGERY, KING'S COLLEGE HOSPITAL.

(With Special Plate.)

THE term "chronic mastitis" is fallacious because it does not allude, as its name implies, to an inflammation of the breast, and also because the clinical signs universally considered to be connected with it mask many and various states of breast hyperplasia. It is a dangerous diagnosis, because these clinical signs hide carcinoma in its earliest stages, advanced carcinoma in rarer examples, and many other states of epithelial hyperplasia.

I believe the want of a proper recognition of these facts has led to the present confusion of opinion as to whether so-called "chronic mastitis" is or is not a prelude to carcinoma. Instead of saying that it is a prelude to carcinoma, I would prefer, to-day, to put the matter thus: The clinical signs on which its diagnosis depends include early and, in rarer instances, late carcinoma, duct papillomata (with which carcinoma is so often associated), as well as many other states of hyperplasia. Hence the danger and inaccuracy that lurk behind these clinical signs.

As a result of my paper I may be accused of demonstrating errors of diagnosis instead of proving that the clinical signs which indicate "chronic mastitis" are applied to various and some dangerous pathological changes. The accusation would be wrong, for the whole profession, including myself, is being misled constantly by these clinical signs, which are totally insufficient to enable any of us to be sure what is happening in breasts that exhibit them. There can be no doubt that the issues are so important that we ought to know precisely what is occurring in these breasts. Let me go more fully into these points.

I have inferred that inflammation and hyperplasia are different processes—an inference that clearly demands that I should say what I mean by inflammation, and by chronic inflammation in particular. Pathologists agree that what is now called "chronic inflammation" is quite a different process from acute inflammation. My conception of acute inflammation is as follows:

Blood corpuscles are aggregated in the blood vessels. There is dilatation of the arteries (commonly preceded by a brief period of contraction), giving rise to more free flow through the capillaries. This arterial dilatation is a purely nervous act that has been proved by Dr. Ninian Bruce to be due to an axon reflex. Other changes are that red and white corpuscles are prone to stick to one another and to the blood vessel wall, and the circulation becomes slow. There is an exudation of plasma, and an exodus of blood corpuscles from the interior of the blood vessels into parts outside them. Also, there is loss of function in an inflamed part; for example, the loss of movements of the cilia of ciliated epithelium (Lister). Lord Lister also stated that the lost movements of the granules in the pigment cells in the frog were another sign of lost function in the inflamed area. But our present knowledge renders pigmentation a much more complicated subject than it was in his time, and so much new work is in progress on this subject and that of acute inflammation that the pigmentary changes may prove, like the arteries, to be due to disturbed function and not lost function.

I have enumerated the changes that are classed together under the term "acute inflammation"; to them, when they last a long time and are less intense in degree, I assign the term "chronic inflammation." That is my conception of chronic inflammation, and I do not apply that term to any other tissue changes. The knowledge that has accumulated of growth, and of the effects of irritation applied directly to cells, has become so important that

Burdon-Sanderson's definition of inflammation (made in 1870) can no longer be accepted as true. He said: "Inflammation is the succession of changes which occur in a living tissue when it is injured, providing the injury is not of such a degree as to at once destroy its structure and vitality." That definition includes too much. In it there is no definition of injury, and there is no limitation of time, nor to the "succession of changes" that occur in tissues as a result of stimulation or irritation.

You may object and say that "Inflammation induces increased blood supply, which induces hyperplasia, and if that be so, therefore inflammation is at the bottom of hyperplasia." My reply would be that increase of blood may be essential to an increase of growth, but I do not admit for a moment that it can induce hyperplasia. I know that Hunter performed a classical experiment upon cocks, by which he intended to show that an increase of blood supply does induce an increase of growth. He transplanted their spurs into their combs, and an enormous growth of the spurs ensued.

In this experiment Hunter assumed many things, among which were that a cock's comb was a more vascular medium than the cock's leg, and that the subsequent excessive growth of the transplanted spur was due to the increase of blood supply it received.

I have repeated Hunter's experiment, and, in addition to transplanting spurs into combs, I placed them subcutaneously in the backs of the birds. The spurs seemed to me to grow equally big in both places. I had to cut short the lives of my birds because their vocal accomplishments disturbed the amenities of King's College and most of the inhabitants in the neighbouring Strand. I came to the following conclusions:

1. That the combs merely consist of a soft almost avascular gelatinous kind of substance that did not bleed at all on incision, and often there was smart hæmorrhage during the removal of the spurs from the legs. The natural blood supply of the spurs seemed greater than that of the combs.

2. That the increased growth of the spurs was due to the want of wear and tear to which they are not subjected in their abnormal situations. In the days of cock-fighting spurs were protected by a kind of thimble which allowed them to grow into formidable weapons of offence; the thimble did not increase their blood supply—it only protected them from the wear and tear of life.

3. That there are other more recently acquired fundamental facts relating to growth that are also involved in this matter, but into which I need not enter.

The formation of keloids that occurs in the scars (and sometimes only in parts of scars) of only certain individuals is an obvious example of hyperplasia, with which the mysteries of growth are more concerned than those of inflammation, with which it is now classified. The healing of a wound is not a process of inflammation, but one of regulated and controlled hyperplasia.

Further, I have pointed out recently that the connective tissue around fibro-adenomata, in their early stages of growth, is in a state of a diffuse hyperplasia that is identical in structure with that of the tumour. The area of this diffuse hyperplasia resembles what is now assumed to be "chronic mastitis," but the altering tissues in the neighbourhood of the fibro-adenomata are really taking part in the formation of the tumours, and are not suffering from an inflammatory process. (See Figs. 1 and 2.)

The truth of the matter is that now we know the problems relating to growth are much more complicated than they were supposed to be in the times of Hunter, and later of Burdon-Sanderson. Although our knowledge of the problems concerning growth is elementary, yet it is great enough to impel us to consider all states of hyperplasia in terms of growth and not in terms of inflammation.

This conception is of immense practical importance when considering pathological changes of the breast in relation to their clinical signs. As an example of this point, I will show you later on a breast that was diagnosed as "chronic mastitis" by one of the ablest clinicians of our time. Besides containing many different states of hyperplasia and cysts (the existence of which he knew), it also contained, totally unsuspected, a fibro-adenoma, a duct papilloma, and carcinoma—all of which were discovered incidentally on

\*The annual address delivered, November 27th, 1924, before the Sunderland Division of the British Medical Association.

making whole sections of this gland. With the exception of generalized nodularity and pain, there were no clinical signs to indicate the presence of any of these lesions. Discoveries such as this are not uncommon when breasts are examined by cutting whole sections for microscopic examination. Our knowledge of breasts cannot be accurate until their examination by means of whole microscopical sections is adopted universally.

I would go still further, and I would apply the term "hyperplasia" instead of "chronic inflammation" to other pathological states. Take, for example, the structure of a tubercle in tuberculosis. I would much prefer it were called a tuberculous hyperplasia and not "chronic inflammation." The lesion is one of pure hyperplasia. There is a giant cell surrounded by epithelioid cells, which are encompassed by an accumulation of lymphocytes, and an old tubercle is surrounded by newly formed fibrous tissue. You may say in surprise and indignation that surely lymphocytes are cells that belong essentially to "chronic inflammation." As a fact their presence is due to the laws that govern hyperplasia. You will remember that Carrel, in the famous address that he delivered before this Association, pointed out that lymphocytes and fibrous tissue cells respectively can grow and multiply *in vitro*.

There can be no doubt that acute inflammation and hyperplasia, different processes as they are, can occur at the same time. As an example, consider what is occurring in acute suppuration. Acute inflammation is present, and within the first hour it may be present alone. After two or three hours hyperplasia of tissue begins outside the centre of disease. Again, can there be a more wonderful state of hyperplasia than that which is occurring in the bone marrow, where the polynuclear leucocytes of suppuration are being manufactured in an enormous number? Nobody has suggested yet that the bone marrow is inflamed in this process.

You may tell me that tuberculous knees are hotter than normal joints, and that sign must always be one of the classical indications of inflammation. I agree it is, and chronic inflammation, as I have defined it, is also present when heat is manifest; but when proper physiological rest is applied to them the increased heat disappears, although tuberculous hyperplasia be still present. I may here point out that a breast suffering from what is now called "chronic mastitis" is usually of normal temperature.

Lastly, when I describe one of the types of desquamative hyperplasia of epithelium, it will be seen that colostrum corpuscles are being formed only in certain ducts of the breast, even when patients are virgins past their menstrual life. As the lesion is local and not affecting the whole breast, the result must be a combined effort of physiological and pathological processes that are operating locally. Hence much more complicated principles are concerned than merely those of inflammation.

I never use the term "chronic mastitis." I say the state is, as may be, either a local or a diffuse hyperplasia of the breast tissues respectively. Sir Humphry Rolleston, at my request, kindly suggested to me the term "mazoplasia."

My paper will be in vain if I cannot make you realize, when you are confronted by a breast which you now imagine to be one of "chronic mastitis," that you are in the presence of intricate problems of hyperplasia, that the clinical signs upon which you depend for the diagnosis of "chronic mastitis" do not convey an accurate conception of what is occurring in the breast before you, and that the life of the patient depends on the accuracy of your conclusions. In every breast that I examine clinically and microscopically my investigation is influenced absolutely by this dominating principle of hyperplasia and in what variety it may be present.

I proceed to give you examples of pathological changes that are included in this nebulous diagnosis of "chronic mastitis," and from them I trust you will see how inaccurate is the term, and how terribly anxious we ought to be when the only clinical signs to guide us are those of nodularity of the breasts and pain. I shall exclude all considerations of decided solitary tumours. The states of hyperplasia I shall describe occur, with some exceptions, mainly in the peripheral ducts, and also in some of the acini related to them.

The larger ducts may less commonly share in these processes, even as far as the nipple. This statement does not exclude the possibility of the hyperplasia occurring in the nipple itself, for it can be filled with secreting acini during lactation to such an extent that the ducts appear to be anatomically of minor importance. I will show that certain pathological changes are very often limited in site to the peripheral ducts and some acini connected with them. This limitation is common to various forms of epithelial and connective tissue hyperplasias, a fact that insists upon the consideration whether these processes are consecutive stages leading from one to the other should the action of the toxic agent be continued.

In order to make myself clear it is essential that I should draw your attention to the histological anatomy of the ducts and acini. Beneath the epithelial lining of the structures there is a layer of unstriated muscle fibres, which is separated from the clastica by a thin layer of a few bipolar cells loosely connected together by a delicate fibrillous tissue. The clastica is mainly limited to the ducts, and only occasionally surrounds acini; more rarely it surrounds a lobule. The delicate cellular fibrillous tissue that lies beneath the layer of unstriated muscle is continued around the acini, whether the clastica is continued around them or not. Outside the ducts and acini there is a layer of fibrous tissue that is in close contact with these structures. It is less dense in character than the supporting fibrous tissue of the breast, and forms the intralobular and pericanalicular fibrous tissue. This layer has almost a physiological connexion with the secreting elements. It often disappears in the breasts of virgins after about 35 years of age, so that the atrophied glandular elements are left in direct contact with the supporting fibrous tissue of the breast.

It is important to state that it is rare to find any type of connective tissue hyperplasia without a corresponding hyperplasia of the epithelium in the ducts or acini concerned; hence its presence may be assumed during the description of connective tissue hyperplasia. "Hyperplasia intra-elastica" is the term I apply to connective tissue hyperplasia that occurs internal to the elastica; "hyperplasia elastica" I apply to the enormous massive hyperplasia that sometimes occurs in the elastica itself; and when hyperplasia occurs in the pericanalicular and intralobular connective tissue, I term it "hyperplasia extra-elastica."

There is one more preliminary point. The best position in which to place a patient for the clinical examination of the breast is as follows: She should lie on a pillow that is placed immediately behind her chest. This position throws forward the breasts, the arms fall downwards with the elbows resting on the couch, and expose the axillae for clinical examination. The breasts and axillae should be examined, and the ampullae, ducts, and acini separately palpated.

I divide the pathological changes I am about to describe into three classes:

- I. Desquamative epithelial hyperplasia.
- II. Non-desquamative epithelial hyperplasia.
- III. In which the epithelial hyperplasia may be desquamative and non-desquamative in the same specimens, and in which the changes in the connective tissues appear to assume greater importance than the changes in the epithelium.

I must firmly impress upon the reader that the processes I describe often overlap each other to such an extent that I can show whole sections of breasts that contain in each respectively fibro-adenoma, duct papilloma, carcinoma, hyperplasia intra-elastica, hyperplasia elastica, hyperplasia extra-elastica, and cysts, as well as other types of epithelial hyperplasia.

#### CLASS I.—DESQUAMATIVE EPITHELIAL HYPERPLASIA.

This class consists of two types—A and B.

##### Type A.

**Pathology.**—In this type there is more commonly a generalized desquamative hyperplasia of epithelium, mainly in the peripheral ducts and also in some of the acini connected with them. It may, however, become

SIR G. LENTHAL CHEATLE: FALLACY AND DANGER OF THE TERM "CHRONIC MASTITIS."

FIG. 1.—A segment of breast removed from a girl aged 16 years. The fibro-adenoma D called for the operation, and irregularity of the breast between A and B was the only palpable clinical sign of a more generalized pathological state. This microscopical whole section of the parts removed shows a distinct macroscopical appearance of the breast between the letters A, B, and that part between the letters B, C, where the breast is normal. At E there is an unsuspected small fibro-adenoma. From F Fig. 2 is drawn. (Natural size.)

FIG. 2.—A low power magnification of the tissue changes occurring at F in Fig. 1. There is a marked extra-elastic hyperplasia, and it is a diffused state of the same changes that are occurring in a localized form in the two fibro-adenomata at D and E, Fig. 1.

FIG. 4.—A vertical whole section of a breast removed for cyst due to "chronic mastitis." At A, C, D, there are three foci of infiltrating carcinoma, and at B there is a multiradicular papilloma in a duct cyst. (Natural size.)

FIG. 5.—Horizontal whole section of breast. The shape is that of a normal breast. The structure of the breast is replaced by diffuse carcinoma, C. A, skin; B, subcutaneous tissue; D, remains of pectoralis major; and E points to one of the infiltrated ligamenta suspensoria of Sir Astley Cooper. (Natural size.)

FIG. 3.—A low power magnification of a peripheral duct in transverse section. The desquamative hyperplasia belongs to Type B of this article. The lower part of the duct wall B at E, C the expanding wall has been parted by and the cell contents are being pushed out into the duct.

FIG. 5.—A low power magnification of a peripheral duct cut in longitudinal section. C, elastica; A, carcinoma cells filling the duct; and at B carcinoma cells are forcing their way from the inside to the outside of the duct.

more obvious clinically at one part or more than one part. All the affected structures are distended by this hyperplasia. The epithelium is proliferating universally from the surfaces of these structures. The cells thrown off are small, irregularly shaped, and desiccated, and are quite distinct in appearance from those thrown off by Type B. Hyperplasia extra-elastica is commonly in association, in which accumulations of lymphocytes are often present. The presence of lymphocytes is by no means an essential feature. Although this state affects most of the gland, there are parts which have not undergone these changes. This state of general epithelial hyperplasia is one of the early stages of cyst formation, Type B being the other. Also, slightly enlarged lymphatic glands sometimes occur in the axilla. Microscopical examination of the breast, and secondary in their centres a diffuse hyperplasia of endothelium to which their enlargement is due. I have seen the same endothelial hyperplasia occurring in lymphatic glands that were secondary to carcinoma of the breast, and secondary to apparently aseptic operations upon animals.

**Clinical Signs.**—On palpation the whole breast is studded by multiple nodules which vary in size, but are seldom larger than a dried pea. The ducts are tortuous, and ampullar can often be felt enlarged. There is no discharge from the nipple. Occasionally the enlarged lymphatic gland may be felt in the axilla. This state attacks married and unmarried women from 30 years of age onwards. It may last for months or years. Usually it has no relation to pain at the periods. The general hyperplasia is not be worse on palpation and when the breast is jarred. Pain is worse on palpation and when the breast is jarred. Pain is due to the distension of ducts and acini. The clinical signs appear local when the pathological changes are more advanced in one part than in other parts. When the changes appear to be local on clinical examination, the only way to be certain of the diagnosis between it and early carcinoma is to cut whole sections of the part removed for examination. How far is this practicable? This investigation is all the more essential when the affected parts are in the upper and outer segment of the breast, where the skin is often normally attached to the underlying breast.

#### Type B.

**Pathology.**—This type usually affects the peripheral parts of the ducts only, or acini only, or peripheral ducts and acini. It may affect mainly one part of a breast, or many quite isolated parts, or may complicate other states of hyperplasia. It attacks married and unmarried women from 30 onwards. As the processes in the ducts and acini are somewhat different, I will describe them separately.

**Ducts.**—In the early stages, what is seen is this: At four or five different spots in the circumference of the ducts the epithelial cells become long and feathery, undergo proliferation, and throw off large and swollen cells, and stain badly with a small degenerated nucleus. In other cells of the same type the protoplasm may stain badly, but the nucleus stains well. The various stages in the development of these large cells from the feathery cells, and demonstrated with certainty. In the later stages the duct surface feathery cells can be seen. One type of cysts arises from this type of epithelial proliferation in the ducts. I will show you in a transverse section of a duct what may happen when it becomes overdistended by this type of hyperplasia. You will see that mechanical rupture of its wall has occurred, and the big swollen cells are being pushed into the parts surrounding it (Fig. 3). In another specimen I saw a large collection of these particular cells lying loose, as it were, in the supporting fibrous tissue of the breast, and I wondered how they had got there. The explanation lies in this very interesting little discovery. I would like to say this: The large swollen desquamated cells of this type resemble colostrum corpuscles. I am confident they are colostrum corpuscles. If so, the origin of the latter in breasts of all ages and stages is clearly from the walls of the ducts and not from the acini, for in all my specimens these cells can be traced in all stages of formation as they arise direct from the duct cells.

**Acini.**—The epithelial cells lining the acini become long and feathery, but I have not seen among them the large colostrum cells that occur in the ducts. Eventually the cells lose their feathery type and become more cubical and spheroidal, and sometimes form columns consisting of four or five cells that grow into the interior of the dilated acinus. Often small, intracystic papillomata of delicate structure are formed. Acinous cysts thus formed may reach a large size. I consider that the pathological changes in Types A and B are premonitory and are preparing the way for many sequences—for example, cysts, stagnation of contents in cysts, papillomata, and even carcinoma.

#### Cystic Breasts.

**Pathology.**—The multiple cysts are a result of the changes described above in Types A and B. Cysts may be general throughout the breast, or more or less local. The smallest cysts, which are microscopic, still exhibit desquamative hyperplasia of epithelium of the type to which they belong. The larger cysts are lined by a layer, sometimes more than one layer, of more or less degenerated epithelium. Whole microscopic sections of these glands form an instructive object of study. I will give five examples. In the first, the breast is riddled with cysts of various sizes. There is no evidence of any intracystic growth. The second contains many where hyperplasia extra-elastica has become so marked as to form small fibro-adenomata. The third contains many cysts, in only one of which I was able to discover a papilloma, which happened to be of the rare uniradicular type. The cyst containing this papilloma was a small dilated duct. The third multiple cystic state (Fig. 4) exhibits one small cyst in which multiple parts of the of the multiradicular type. In three separate parts of the breast there are foci of carcinoma in which epithelial cells are infiltrating the fibrous tissue of the gland and fat in signs to indicate the presence of these complications, which were only incidentally discovered on microscopic examination of whole sections. The breast was removed upon a diagnosis of "cysts due to 'chronic mastitis.'" Fourth, there are other cystic breasts in which papillomata commonly originate. There is a fifth and more rare state in which carcinoma is incidentally discovered in large cysts when whole sections have been made.

I have the breasts of five separate patients which show remarkable and surprising pathological changes. On making whole sections of these breasts I found totally unsuspected carcinoma within large cysts. The cysts contained clear fluid and their walls were soft. What makes these observations so important is that medical men are apt to conclude that large cysts are never dangerous. Moreover, when they tap these cysts, they are content to regard them as simple when they extract a clear fluid and discover that their walls and surrounding parts of the breast are soft. Although I agree that large cysts, as a rule, are not dangerous, I do not consider that small cysts are reliable and the softness of surrounding tissue, are indications of complete safety. I am convinced that small cysts are a danger either in them or by a malignant small cyst formation, which I will describe later on.

**Clinical Signs.**—Over the whole breast multiple nodules occur, and vary from the size of a pea to that of an ordinary hen's egg. The larger nodules fluctuate definitely. Smaller ones are so decidedly elastic that no doubt could be entertained of their fluid contents. It is impossible to declare on clinical signs alone that there are no intracystic growths present. The fluid nature of their contents obscures the presence of internal growth. As a rule, on the formation of cysts pain disappears and is substituted by a feeling of general discomfort. Generally there is no discharge from the nipple, though gentle pressure on the breast may induce a clear or greenish discharge from the nipple. Lymphatic glands are not as a rule enlarged. When present, they exhibit endothelial hyperplasia, unless one of the cysts contains a carcinoma, when the gland might contain epithelial cells. Hence in doubtful states it would be well to remove the enlarged lymphatic gland and determine its contents by microscopic examination.

## CLASS II.—NON-DESQUAMATIVE EPITHELIAL HYPERPLASIA.

## A. Diffuse Carcinoma.

**Pathology.**—One would consider that advanced diffuse carcinoma could never be diagnosed as "chronic mastitis," but such is the fact. I will describe a breast of one patient, and the breasts of another.

Turning to the first, the breast appears of normal shape and size (Fig. 5). Curiously enough, there is no sign of breast tissue to be seen. The site of the normal breast is entirely occupied by a diffuse carcinoma. Epithelial cells have an alveolar arrangement. They completely fill spaces divided from each other by a thin network of fibrous tissue. The spaces vary in size, and are irregular in shape. There is no solitary lump. At many points the bases of the ligamenta suspensoria are attacked by carcinoma. Their attachment to the skin gave rise to the general nodularity which led to the diagnosis of "chronic mastitis." Lymphatic glands in the axilla contained carcinoma, although clinically they could not be distinguished.

In the second patient both breasts were affected by diffuse carcinoma. There were no solitary lumps. Carcinoma had invaded the bases of the ligamenta suspensoria, which gave rise to the general nodularity of the breasts. The pathological states of these breasts were the same and in no way resembled the remarkable appearances seen in the breast of the first patient. There was a primary carcinoma in each breast, which had spread in the usual method. Parts of the gland could be easily demonstrated in different parts of these breasts. Lymphatic glands in the axillae contained carcinoma, although they could not be distinguished clinically.

**Clinical Signs.**—The shape and the size of breasts belonging to this type remain unaltered. Careful palpation reveals diffuse puckering of the skin, general nodularity, and the absence of a decided solitary tumour. The breast may move freely over the pectoral fascia, or become fixed to it. Lymphatic glands in the axillae contain carcinoma, although their detection may not be possible clinically. The diagnosis is often rendered difficult by the fact that the patients may be fat. The two patients to whom I have referred were under the care of highly experienced observers, who, although they were always worried about these women, kept them under observation for eight months and eighteen months respectively. Doctors and patients were convinced that the states of the glands had not altered during these times.

## B. Local Carcinoma.

**Pathology.**—I am about to describe what I believe to be a common method by which carcinoma begins. A localized collection of peripheral ducts and acini are distended by well stained malignant-looking cells. After careful search made of whole sections of a breast, small definite areas can be seen in which epithelial cells of precisely the same appearances have invaded the surrounding tissue. The distended ducts and acini in parts are more or less cystic and contain a clear fluid. The duct cysts may contain multiradiolar papillomata. The acinous cysts may contain sessile growths, which project into the interior. I have not yet seen an early stage of carcinoma in which the peripheral duct or ducts were not implicated in the process. The epithelium of these cysts is identical in appearance with those that have invaded the surrounding tissue. It may be that the epithelial cells which have undergone hyperplasia may exist within the ducts and acini for a considerable period before the invasion of the surrounding parts occurs. I am led to believe, by what I have shown you in ducts and other breasts, that the invasion may be the result of accidental rupture of the walls of the small ducts or acini, and because the cells are malignant and capable of proliferation they continue to grow and spread to other parts of the body. Should the epithelial invasion of surrounding breast structures occur in the middle of the lesion, the ligamenta suspensoria are not affected and enable the diseased area to be pushed about without puckering the skin. The tumour may reach a large size before puckering of the skin can be demonstrated. I am sorry to say that breasts containing the early stages of this type are nearly always diagnosed as "chronic mastitis." Carcinoma may begin and spread also in a pre-existing cyst small in size.

**Clinical Signs.**—There is usually a history of pain, yet pain may be absent at the time of examination. When present it is made worse on palpation. There is nodularity of the affected area. There is no puckering of the skin in the early stages. It is certain to appear later, but the disease may be advanced beforehand. Enlargement of

carcinomatous lymphatic glands is usual except in the earliest stages of carcinoma, when it is limited within ducts and acini.

## C. A Diffuse Non-desquamative Hyperplasia of Epithelium.

**Pathology.**—There is a type of non-desquamative hyperplasia of epithelium which can affect only one peripheral duct and some of its acini and sometimes none of its acini. In other patients a non-desquamative hyperplasia of epithelium somewhat akin to this state can affect whole lengths of ducts secondary to Paget's disease of the nipple and to other forms of carcinoma of the breast. In those breasts in which only one peripheral duct and some of the acini are affected these structures are full of epithelial cells whose nuclei and protoplasm stain well, with no appearance of desiccated cells, nor of the large, swollen, colostrum-like cells, and look decidedly malignant. The appearances seen in these ducts lead me to believe that carcinoma in an early stage can exist for long periods in ducts which do not show epithelial transgression of their walls. Epithelial cells in the earliest stages of carcinoma are heaped up in ducts and acini, and distend them as if they were waiting for the final accident of rupture, through which they can escape into the surrounding tissue. Precisely similar changes are seen in the early stages of far cancer in mice. This observation is supported by the appearances noted in a duct whose epithelial hyperplasia belongs to this type (Fig. 6). This duct is distended by non-desquamative epithelial cells; at one part of it there is a solution of its continuity, and through which non-desquamative epithelial cells are pouring into the connective tissue, and carcinoma is undoubtedly present. It is most instructive and interesting to compare this ruptured carcinomatous duct with that duct in which the rupture occurred from overdistension, by the heaping up within its interior of large desquamated cells of colostrum type (see Fig. 3).

**Clinical Signs.**—The distended ducts and acini give rise to marked local nodularity. Pain is associated with the state and is referred to the site of nodularity, and is made worse on palpation. There is no discharge from the nipple, and lymphatic glands may be enlarged in those examples where the epithelial cells have passed their natural boundaries. This is one of the types that are so important to remove at the earliest possible moment. As a rule it comes for operation after it has passed through the usual period of diagnosis of "chronic mastitis."

## D. Papillomata.

**Pathology.**—Although one papilloma may exist in a breast, it is uncommon, and as a general rule it contains many papillomata. Where one papilloma exists, it is situated generally in an ampulla. Where many exist, one of them is usually found in the ampulla and the rest are scattered diffusely throughout one duct or more than one duct. I have whole sections of a breast in my possession that contain two ducts and their ampullae full of papillomata. Altogether over 170 can be counted in one of the sections. The papillomata belonging to this class are multiradiolar as a rule—that is to say, each papilloma may arise from many points in the wall of the duct. The epithelium in the tops of these papillomata coalesce. Sometimes the epithelial cells form columns which unite at their tops, also masses of epithelial hyperplasia arise directly from the lining of the duct and give rise to sessile tumours. The connective tissue in papillomata may be one of three types. It may consist purely of intra-elastic connective tissue; it may contain stalks of extra-elastic tissue, and hence contain the elastica in the centre of the stalk; and thirdly, the latter type may also contain an intra-elastic hyperplasia. It is a very interesting fact that papillomata are frequently present in the parts of those ducts which lead directly into the mass of spreading carcinoma. Papillomata often show evidence of past haemorrhage into their structure and into their ducts. I have no time to discuss the problem as to whether papillomata can become malignant. They may grow to enormous proportions. A uniradiolar papilloma is a rare occurrence.

**Clinical Signs.**—The general appearance of a breast is normal when the papillomata are small. When they become large they may deform the breast and even protrude from a duct orifice on the surface of the nipple. There is often a history of pain, not of a severe character. Sometimes there is a history of discharge of blood or serum from the nipple. I possess a specimen the clinical signs of which had lasted eight years and a blood discharge from the nipple was only noticed once, and that was in the middle of its history. When haemorrhage from the nipple occurs, it is a classical sign of papillomata or carcinoma of a duct. Papillomata can exist, however, without inducing haemorrhage from the nipple. On palpation one ampulla or more than one ampulla may be felt enlarged, palpation of which may induce pain and haemorrhage, or a discharge of serum. When the duct is full of papillomata an enlarged ampulla can be felt, and its ducts and branches can be distinguished tortuous and enlarged right down to the periphery. The general sensation on palpation is one of nodularity, and more than one duct may be affected.

**CLASS III.—IN WHICH EPITHELIAL HYPERPLASIA APPEARS TO BE, HISTOLOGICALLY, OF LESS IMPORTANCE THAN THE HYPERPLASIA OF THE CONNECTIVE TISSUE.**

#### A. Hyperplasia Elastica.

**Pathology.**—In this state there is a universal massive hyperplasia elastica throughout the whole lengths of all the ducts and those acini that happen to be surrounded by elastica. It is of enormous and surprising proportions and density. Hyperplasia elastica is accompanied by a loose hyperplasia extra-elastica. One never extends beyond the limits of the other, and their limit is the general supporting connective tissue of the breast. The state I discovered incidentally, on making whole microscopical sections of carcinomatous breasts, and of non-desquamative hyperplasia of epithelium (Type C). In one of the carcinomatous patients primary malignant disease and massive hyperplasia elastica were present in both breasts. Less marked hyperplasia elastica occurs in ducts that contain carcinoma and in ducts that contain a highly suspicious type of non-desquamative epithelial hyperplasia.

**Clinical Signs.**—Massive hyperplasia elastica gives rise to multiple solid nodules over the whole breast, which are due to tortuous, thickened ducts and the affected acini. The condition is painless, and I do not know how it can be diagnosed by clinical examination.

#### B. Hyperplasia Intra-elastica.

**Pathology.**—Hyperplasia intra-elastica affects mainly peripheral ducts and acini, sometimes picking out a terminal duct and its lobule. Its presence is very marked and always local. I have never seen it generalized. In the early stages the loose, delicate, cellular, fibrillous tissue inside the elastica undergoes diffuse hyperplasia. It may be evenly distributed, or it may be more marked at one place than another. The fibrillous matrix supports isolated bipolar or stellate cells. Here and there the layer shows a marked tendency to grow larger and give rise to a small intra-elastica fibro-adenoma, an intra-elastica papilloma, or only an irregularity of its surface. It usually undergoes degeneration, when only an occasional cell can be stained to prove its cellular origin. It is not a common state, and it is often associated with carcinomatous breasts. Certain types of fibro-adenomata are derived from this tissue.

**Clinical Signs.**—Hyperplasia intra-elastica generally occurs in women over 35 years of age. Enlarged ducts and acini give rise to local nodularity of the breast. The breasts are nodular, but there are no special clinical signs by which the state can be diagnosed. I have discovered it only on making large microscopical sections and during their examination for other diseases.

#### C. Hyperplasia Extra-elastica.

**Pathology.**—This type is found distributed generally throughout the gland, or only in association with the formation of the extra-elastica type of fibro-adenoma; it is an essential part in the formation of this tumour. It

is unnecessary to do more than allude to the general state of hyperplasia extra-elastica. I will deal only with the local state in connexion with the formation of fibro-adenoma. On cutting the breast in half, so that the incision passes through the affected and normal parts of the breast, a difference in the structure between these parts is at once evident macroscopically. The normal part of the breast appears white, the affected part appears lightish grey. The affected part usually occurs in the smaller ducts and acini at the periphery of the gland, and macroscopically looks definitely limited. Microscopically the limitation is not so definite. On cutting whole sections of these breasts for microscopical examination three things may be seen in the affected part: First, the fibro-adenoma, which attracts attention to the breast, is quite obvious. Secondly, a small, definite, unsuspected fibro-adenoma may be discovered in juxtaposition to it, or separated from it by a small area of breast tissue. Thirdly, the parts that appear lightish grey on macroscopical examination show marked hyperplasia extra-elastica, which is an essential part in the growth of this tumour. The parts of the breast that appear white are normal on microscopical examination.

**Clinical Signs.**—The fibro-adenomata are seen mainly in young people from 15 to 25 years of age, but may occur in breasts of much older people. Attention is drawn to the breast by the fibro-adenoma. On palpation the surrounding parts are nodular; the nodules are about the size of small shot. There is very little pain connected with this type, and it is usually localized to one segment of the breast.

I have not dealt with the management and treatment of these diseases, for these reasons—namely, that the correct management and treatment frequently depend absolutely on the most careful judgement and laborious and precise preliminary microscopical examination. The detailed description would take me so long that I must reserve this part of my subject for another time.

Finally, I hope I have said enough to show you that the term "chronic mastitis" is a misnomer, and does not correctly indicate the states to which it is universally applied; that the clinical signs on which its diagnosis now depends can only indicate the possibility of many, without specifying one, of the various lesions they hide, and that these lesions may include carcinoma in its earliest as well as in its late stages.

## PSICAINE: A NEW LOCAL ANAESTHETIC.

BY

A. J. COPELAND, M.A., M.B., D.P.H., B.Sc.,

ERNEST HART MEMORIAL SCHOLAR, BRITISH MEDICAL ASSOCIATION.

(From the Pharmacological Laboratory, Cambridge.)

THIS cocaine substitute is an optically active isomer of ordinary cocaine prepared by Willstätter in collaboration with the firm of E. Merck of Darmstadt.

Cocaine is formed from the combination of l-ecgonine with methyl alcohol and benzoic acid. L-ecgonine contains four asymmetric carbon atoms, so that sixteen optical isomers are possible, eight of which are the mirror images of the other eight. One isomer of l-ecgonine is d-ecgonine, which differs from the former in the arrangement in space of the H and OH groups. D-ecgonine is built up from this in exactly the same way as cocaine is built up from l-ecgonine, and the acid tartrate of this substance is known as "psicaine."

In Germany psicaine is approximately twice as expensive as cocaine, but it is said to have double the anaesthetic power, half the toxicity, and to be free from addiction properties. Psicaine is freely soluble in cold water up to 25 per cent., and is not precipitated by saline solution, Ringer, nor by proteins.

On the cornea psicaine in my experiments has approximately one-sixteenth the anaesthetic power of cocaine. The minimal effective concentrations to give complete anaesthesia after instillations lasting one minute are—for cocaine 0.25 per cent., and for psicaine 2.5 per cent.; on the other

hand, a 0.5 per cent. solution of cocaine and an 8 per cent. solution of psicaine are equally effective in giving complete anaesthesia averaging thirteen minutes under the same experimental conditions. Psicaine moderately dilates the pupil in rabbits for twenty-four hours; it causes slight vascular congestion, but no drying of the cornea.

In my earlier experiments for determining the activity of local anaesthetics on nerve fibres I chose the vagus, and estimated the duration of the loss of conductivity of the cardiac fibres. In the present investigation I have adopted also the method of using true sensory nerves. The most satisfactory nerve in rabbits was found to be the anterior crural, both because of its small size and the ease with which a long portion can be separated.

For the quantitative comparison of the anaesthetic action of different local anaesthetics it is necessary to choose some nerve peripheral stimulation of which produces an effect which can readily be estimated. It is clearly of great importance that this nerve should be small in size. The American and German observers have, for the most part, used the sciatic nerve of animals; the objections to this are obvious, because the nerve is so big that before a complete anaesthesia is produced the drug has to penetrate a considerable thickness of nerve tissue—that is to say, the rate of penetration or absorption comes into play. When a drug is injected subcutaneously it acts on only the very finest of the nerve fibrils, and therefore to obtain any result comparable with the effect of a subcutaneous injection the finest nerve possible should be chosen for experiment.

The method adopted is a modification of that recently described by Schnitz and Loevenhart.<sup>6</sup> The rabbit first receives an injection of urethane (1.5 gram per kilo), and one hour later ether is administered and a cannula is inserted into the trachea. The anterior crural nerves are isolated and are cut as near to the periphery as possible. Ether is now discontinued, the urethane giving adequate and uniform anaesthesia. Each anterior crural nerve is held by a protected electrode at a point 2 cm. from the cut end, and is excited by the weakest current necessary to produce a definite effect on respiration. A tambour connected to the tracheal cannula records the respirations on a moving drum. In all experiments, both with the vagus and with sensory nerves, the drug is applied over 1 cm. of nerve for thirty seconds. The nerve is stimulated immediately after painting, and subsequently every few minutes, the absence of any effect on respiration denoting complete anaesthesia. By using a double key in the secondary circuit the other anterior crural nerve can be excited by the same current and serve as a control, and subsequently used for a comparative test with another drug.

The results of experiments given in Table I show that the activity of psicaine compared with that of cocaine and tutocain is very weak for both sets of fibres. Novocain in 0.05 per cent. solution has the remarkable action of paralyzing sensory nerve fibres in a degree equal to that of cocaine, but in double this strength it has no effect on vagal cardiac fibres. Dixon has shown<sup>7</sup> that cocaine has certain specific effects in that it paralyzes sensory fibres before motor in mixed nerves, and efferent before afferent fibres in the vagus. Novocain has a strong affinity for sensory fibres and relatively little action on the cardiac fibres of the vagus.

TABLE I.—Effect of Local Anaesthetics on Nerve Fibres.  
(Figures refer to the duration of complete loss of conductivity, in minutes.)

	Cocaine Hydrochloride.	Tutocain.	Psicaine.	Novocain.
Vagus nerve: cardiac fibres	0.1 % 12	0.1 % 10	0.1 % 5-8	0.1 % 0
Anterior crural nerve: sensory fibres	0.05 % 15-20	0.05 % 5-8	0.05 % 0	0.05 % 15-20

The toxicity of psicaine was estimated by determining the minimum lethal doses for rabbits, guinea-pigs, and mice, and also, in rabbits, the minimal doses required to produce convulsions lasting five minutes. The results are given in Tables II and III.

TABLE II.—Minimum Lethal Doses Compared.

	Cocaine.	Psicaine.	Novocain.
Rabbit— Intravenous: 1 per cent. solution (1 c.cm. in 18 s.ccs.)	mg. per kilo. 12*	mg. per kilo. 1†	mg. per kilo. 90
Subcutaneous: 5 per cent. solution	75 (200*, 93†)	40	600
Guinea-pig— Subcutaneous: 2 per cent. solution	30	40	Ove: 350
Mouse— Subcutaneous: 2 per cent. solution (dose in mg. for .0 gm. mouse)	5	7-10	18

\* See Reference 11.

† See Reference 6.

TABLE III.—Minimum Convulsant Dose for Rabbits.

	Cocaine.	Psicaine.	Novocain.
Intravenous: 1 per cent. solution (1 c.cm. in 18 s.ccs.)	mg. per kilo. 8	mg. per kilo. 8	mg. per kilo. 45
Subcutaneous: 5 per cent. solution ...	40	37-40	120

The figures for cocaine given in my previous paper<sup>9</sup> have been modified, and represent the results of experiments made with a sample of cocaine hydrochloride having a melting point of 182° C. (normal 183° C., Martindale).

The Abbott Laboratories, Chicago, U.S.A., the manufacturers of butyn, inform me that they have found "considerable variation in the toxicity and efficiency of different samples of cocaine." They consider that the inequality of samples probably accounts for discrepancies in the results obtained by different investigators, and they suggest that there may be a relation between melting point and toxicity.

In rabbits psicaine, injected subcutaneously, was found to be more toxic than cocaine, whereas injected intravenously the two drugs are of almost equal toxicity. Guinea-pigs and mice are relatively less susceptible to psicaine.

Both cocaine and psicaine give rise to symptoms identical in character though not in degree. Experiments on frogs show that psicaine is a more powerful stimulant than cocaine, since it will more readily increase reflexes and will even produce convulsions, which cease when the cerebrum is destroyed. In rabbits, following a preliminary stage of excitement during which reflexes are increased, there is a sudden tonic spasm, and this is succeeded by a stage of marked clonus in which there are violent spasms of the limb muscles, together with twitchings of the muscles of the head area. The head is retracted and the corneal reflex is lost. With larger and lethal doses the clonic spasms are very violent and are quickly followed by death from failure of respiration. Convulsions do not occur when the cerebrum is destroyed, nor after the administration of a general anaesthetic.

The irritant effect of psicaine is less than that of cocaine, and for practical purposes should not be of any significance. In rabbits 0.5 c.cm. of a 10 per cent. solution of psicaine injected subcutaneously causes slight hyperaemia, followed by thickening lasting two days and some desquamation on the fifth day, whereas cocaine in similar concentration produces ecchymosis and thickening lasting three days, followed by scab formation.

Psicaine has relatively little effect on blood vessels, and its action suggested that psicaine would not cause any swelling of the nasal mucous membrane. This, however, is not the case in the cat, since, using my perfusion method,<sup>10</sup> it was found that after an application of a 5 per cent. solution of psicaine lasting twenty-five minutes the mucous membrane became so swollen as almost completely to obstruct the flow of fluid—an effect which lasted for several hours.

In this series of experiments I have been unable to verify the claims for efficiency and low toxicity which have been made for psicaine. If these experimental results are confirmed psicaine is unlikely to be useful as a substitute for cocaine.

I desire to express my thanks to the Medical Research Council for the special grant it made for the expenses of this research, and to Professor W. E. Dixon, to whom I am greatly indebted for help and advice throughout the investigation.

## PSICAINE: AN ARTIFICIAL COCAINE.\*

BY

E. WATSON-WILLIAMS, M.C., CH.M.,  
ASSISTANT SURGEON, EAR, NOSE, AND THROAT DEPARTMENT,  
BRISTOL ROYAL INFIRMARY.

PSICAINE is said to be the acid tartrate of a pseudo-cocaine, a dextro-rotatory artificial isomer of natural cocaine.<sup>1</sup> (Formula,  $C_{17}H_{21}O_4N$ ; molecular weight, 453; alkaloid content, 67 per cent.). It is a white crystalline powder, very soluble in hot water, soluble in cold water up to 20 per cent.; the solution is acid in reaction, 1 per cent. solution giving a rather pinkish orange tint with dimethylamino-azo-benzene—pH about 3.3; the solution is also dextro-rotatory. (This is mentioned, as other properties of the substance I have examined differ somewhat from those described in Continental reports.) The powder is sparingly soluble in alcohol.

**Anaesthesia.**—Applied to the nasal mucous membrane a 5 per cent. solution gives very good anaesthesia. As compared with 5 per cent. solution of cocaine hydrochloride, the time taken for full anaesthesia is rather longer; the depth of anaesthesia ultimately obtained is the same. The duration of anaesthesia without adrenalin is over fifteen minutes, after packing. If 7 per cent. solution is used, the time required for anaesthesia is practically the same as with 5 per cent. cocaine hydrochloride solution. (The alkaloid content of 7 per cent. psicaine solution is 4.7 per cent., that of 5 per cent. cocaine hydrochloride solution being 4.5 per cent.) I have made over fifty observations with uniformly good results, performing such operations as puncture of the antrum, canterization, etc. I have not found that the anaesthetic value is twice that of cocaine as claimed.

**Toxicity.**—No cases of toxicity in the human subject have been brought to notice. Experiments have shown that doses up to 70 mg. do not produce excitement or fainting when injected into men.<sup>1</sup> This dose (containing less than gr. 3/4 of alkaloid) is too small for deductions of value; many men might escape symptoms after the same quantity of cocaine.

**Shrinkage.**—Psicaine is said to be a vaso-dilator, but I have found uniform good shrinkage after spraying the nose with my 5 per cent. solution. This strength also checks bleeding. If it is desired to use adrenaline the solutions mix well.

**Irritation.**—I have found no case of primary or late irritation with solutions of the strengths described.

**Habit Formation.**—In common with all cocaine substitutes, psicaine is said not to lead to addiction. Deductions from animal experiments support this view—the dose required to produce excitement would probably be so near the lethal dose as to prevent the drug ever making a popular appeal.

**Stability.**—A 5 per cent. solution of psicaine grows "moulds" just as does cocaine solution; the addition of 1/4 per cent. salicylic acid prevents this. Time has not allowed an investigation of keeping powers; the solution is unaltered after two months. Psicaine can be boiled for

five minutes, or steamed for an hour, with only slight loss of power; fifteen minutes in the autoclave at 134° C. seriously diminishes the anaesthetic power and the experimental toxicity.

**Dangerous Drugs Acts.**—It appears that psicaine comes under the Dangerous Drugs Acts. (The Home Office is investigating this point, and will give a decision when the work is complete.)

**Experimental Work.**—Subcutaneous injection into guinea-pigs was chosen as a method of comparison. The minimal lethal dose in 5 per cent. solution was found to be 53 mg. per kilogram. The toxicity is therefore 19 kilograms per gram of psicaine (the toxicity of 5 per cent. cocaine hydrochloride is 25 kilograms per gram). The toxicity figure is affected by the large proportion of acid in the molecule—just under a third. In kilograms per gram of alkaloid, the toxicity is 28, the same as that of cocaine in 5 per cent. cocaine hydrochloride solution. In 1 per cent. solution, the toxicity of psicaine is 18 kilograms per gram. The new isomer therefore appears to have no advantage over the natural alkaloid as regards toxicity measured by the minimal lethal dose. The minimal convulsant dose seems to be almost the same as the minimal lethal dose: it was practically impossible to produce convulsions without killing the animal. Assuming that the same holds good in man, and further that there is some relationship between the dose required to produce excitement, nausea, fainting, etc., and that required to produce convulsions, it is seen why I consider the drug unlikely to become one of addiction: the dose necessary for excitement would be dangerously high—that is, psicaine probably has a high "danger ratio." This is important, since, if so, we shall not be warned when our clinical dosage is getting dangerously large. No one should use psicaine who has not acquired with the much safer (from this aspect) cocaine hydrochloride practice in safe dosage. When death occurs, it is from respiratory failure, the heart continuing to beat after the respirations cease. Under ether anaesthesia, deep enough to abolish reflexes, convulsions do not occur, but the same dose kills the animal, respiration gradually failing; it is not, in fact, the convulsions that cause death.

## Summary.

1. Psicaine is the acid tartrate of an artificial isomer of cocaine. It is soluble in water, giving a definitely acid solution. The solution is not harmed by brief boiling. It requires the addition of salicylic acid to prevent the growth of moulds.
2. Used in the nose, 7 per cent. psicaine solution gives anaesthesia identical with that produced by 5 per cent. cocaine hydrochloride solution. The anaesthetic value of the new alkaloid is the same as that of natural cocaine.
3. The same "shrinkage" as is seen with cocaine is found in using psicaine.
4. The experimental toxicity of psicaine in 5 per cent. solution is three-quarters that of cocaine hydrochloride; the toxicity of the new alkaloid is therefore identical with that of cocaine.
5. It is probable that excitement, fainting, etc., will not be so readily produced by psicaine as by cocaine; it may therefore be useful in susceptible persons.
6. For the same reason psicaine should not be used except by those well accustomed to use cocaine; the dose of psicaine should not exceed that found safe with cocaine.
7. Psicaine is a "dangerous drug."
8. The price of psicaine has not yet been published.

I am indebted to Professor Walker Hall for permission to use the Pharmacological Laboratory of Bristol University for the experimental work on psicaine; and to Messrs. Merck of Darmstadt for supplies of the drug.

# THE TREATMENT OF PERFORATED GASTRIC AND DUODENAL ULCERS.

WITH A REPORT ON FORTY CONSECUTIVE CASES.\*

BY

G. PERCIVAL MILLS, F.R.C.S.,

ASSISTANT SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM.

This paper is a plea for the performance of gastro-jejunostomy whenever possible at the time of operation for perforation. Beginning with some apprehension, I have been led to do so more and more frequently with increasing experience, and I now regard it as almost a routine part of the operation.

The cases analysed below are all those I have treated in hospital since my return from the war: 16 were duodenal, 15 pre-pyloric, 5 in the body of the stomach, and in 4 the situation of the ulcer is not stated in the notes. There were 38 males and 2 females.

## Treatment.

Every case but one was operated on. This patient was moribund on admission, and failed to rally with treatment. The death is included in the mortality statistics. In early cases, seen within about twelve hours of perforation, suture of the ulcer and gastro-jejunostomy was performed without drainage of the peritoneum, except in three instances of very severe soiling, in which a suprapubic drain was put to the bottom of the pelvis. I have long discontinued drainage through the main wound. The same treatment was adopted in a few late cases in which the patient, in spite of long perforation, was still in good condition. In the majority of late cases suture of the ulcer and pelvic drainage was all that was attempted. A single row of sutures covered by omentum was used, and this proved mechanically efficient to prevent further leakage. I believe it is waste of valuable time to put several rows of sutures.

## Mortality.

Of the whole series 11 died, including the case not operated on—a gross mortality of 27.5 per cent.

Of 22 cases in which immediate gastro-jejunostomy was done, one died—a mortality of 4.5 per cent. The death was due to pneumococcal peritonitis seven days after operation.

Of 17 cases in which suture and drainage without gastro-jejunostomy were done, 9 died—a mortality of 52.9 per cent. This high mortality, of course, reflects the fact that the operation was reserved for the worst cases. Five of them died within twenty-four hours of operation of peritoneal shock, three a few days later from peritonitis, and one from acute nephritis and uraemia.

A striking fact about the series is the complete absence of what I used to regard as a common complication—subphrenic abscess. I attribute this to the fact that I put no drainage tubes into the upper abdomen. It might be supposed that subphrenic abscess would be commoner in these circumstances, but clearly the reverse is the case, for since I gave up draining the upper abdomen I have had no subphrenic abscess.

## End-results.

All the patients operated on over six months ago were written to, and several were seen personally. Of the 29 survivors 22 were traced.

*Cases without Gastro-jejunostomy.*—Traced 8, perfectly well 1, still serious gastric trouble 5, relieved by subsequent gastro-jejunostomy 1, died of carcinoma 1. Thus of eight cases only one was cured.

*Cases with Gastro-jejunostomy.*—Traced 14, perfectly well 10, at work but some gastric discomfort at times 4.

## Commentary.

The difference in these end-results is very striking, and shows clearly the advantage of performing gastro-jejunostomy at the time of perforation whenever the patient is in a condition to stand it. Moreover, there is no doubt that with gastro-jejunostomy the patients do better and

have a shorter convalescence than without it. A perforated ulcer is an active ulcer, and it is only natural that to put it at rest should increase the patient's chance of recovery. On the other hand, to do more than is absolutely necessary to a patient suffering from a grave abdominal emergency is to invite certain criticism that the immediate mortality will be increased. If my mortality for the whole series, however treated, is greater than the average, mortality for perforating ulcer, my method stands condemned, and this is why I have been careful to state my gross mortality of 27.5 per cent., which is, I believe, less than the average.

Obviously, considerable judgement is required to decide when to perform gastro-jejunostomy in these cases, but I find from my notes that I have gradually come to do so more and more frequently. Of the last 15 cases operated on I have performed gastro-jejunostomy in 13; all of them recovered, while the two in which I did not do so died.

# CONJUNCTIVITIS IN THE TROPICS.\*

BY

ROBERT H. ELLIOT, M.D., F.R.C.S.,

LIEUTENANT-COLONEL I.M.S.(RET.).

I was once told by a surgeon with many years of tropical ophthalmic practice behind him that he did not recognize such a thing as tropical ophthalmology. Such a position premises to my mind a great lack of perception and of imagination. Tropical practice differs so materially from that in temperate climates as to demand a very special study in order to fit a man for success. We are all of us, as we grow older, conscious of regrets for lost opportunities, but there is no department of ophthalmology which brings up to my mind more often or more acutely the sense of what I might have done and did not do than the study of inflammations of the conjunctiva. I feel that the young man who starts his ophthalmic work in the tropics, awakened to an appreciation of the avenues of research opened up by this line of study, has great possibilities in store for him. With the view of stimulating the interest of some of the younger men in this very interesting subject I propose to review it in a more or less summary manner, and to indicate some of the lines along which I think that research can profitably be conducted.

There is another side to the question. The expansion of our colonies and the movement of great bodies of men to and from the tropics during the war has brought tropical disease to our very doors, and has stimulated an interest in the subject amongst our own medical men practising in Great Britain and in its temperately situated colonies. It is my hope that this bare outline of a great subject may therefore be of some interest to them too.

The habits of the residents in tropical lands, and the climatic conditions which prevail there, are favourable to the implantation of germs within the conjunctival sac and to their growth on its lining membrane. Sun, dust, and wind constitute a triad of evil influence adverse to the maintenance of conjunctival health. All who have lived in Eastern countries are conscious of the drying up of the skin and the rapid exfoliation of its surface layers which are experienced in the hot weather, and which are greatly aggravated when the hot air is in motion, and especially so when it is laden with dust, as it so often is in tropical lands. It used to be suggested that the epidemics of conjunctivitis with which every tropical worker is so familiar are due to the infection of the conjunctivae of the population by germ-laden air. As a matter of fact, the majority of the organisms responsible for the Eastern epidemics of ophthalmia are non-sporing, and we know by experiment that such are easily killed by drying. I will revert to this subject later on, being content here to lay stress on the view that the action of dust, like that of heat and wind, is probably traumatic, abrading the surface epithelium, causing local congestion, and so preparing the membrane for the growth of pathogenic organisms.

\* Abbricated from a paper read before the Birmingham Branch of the British Medical Association, November 23rd, 1924.

\* A lecture delivered at the London School of Tropical Medicine on October 23rd, 1924.

It is not always easy in studying epidemics to eliminate other factors and so to concentrate attention upon those which are most vital. This has, however, been done for us most admirably by Sichel in his investigation of an epidemic of conjunctivitis which occurred on Christmas Island. The climate in this locality shows a well marked wet season (January to May), and an equally distinct dry season (May to December), whilst the temperature is extraordinarily uniform. The mean annual temperature is 80.7° F., the extremes in the monthly averages throughout the years under observation showing a difference of only 2°, whilst the diurnal range does not exceed 14°. The industry of the island is the production of phosphate of lime; the phosphate quarries reflect the sun and cause an extreme glare, whilst the phosphatic dust is extremely irritating. Complete meteorological and hospital records were available for a period of fourteen years. It was thus possible to construct charts showing the close relationship existing between dry weather and the epidemics of conjunctivitis. The influence of glare and dust upon the causation of inflammations of the conjunctiva is clearly proved. The elimination of the temperature factor is most valuable and instructive.

The epidemics of conjunctivitis with which tropical practitioners are so familiar appear, wherever they occur, to have certain common and very definite characteristics. They have probably been better studied in Egypt than anywhere else in the world, but it would seem probable that what is true of them there is equally true, with minor variations, throughout the tropics. They present certain features of interest which should be carefully borne in mind—namely, (1) the great variety of organisms met with in these epidemics; (2) the very definite subdivision of what at first sight might be taken for a single epidemic into a number of subepidemics, each of which shows its own curve of rise and fall in more or less independence of the others; and (3) the curious evenness with which the same class of subepidemic repeats itself at the same time in each successive year, subject of course to variations in intensity, duration, etc., from year to year.

To illustrate these statements I may say that, with the exception of the conjunctivitis of Morax-Axenfeld origin, Meyerhof found that all the forms of acute ophthalmia in Egypt (inclusive of those of gonococcal, Koch-Weeks, streptococcal, pneumococcal, and diphtherial origin) become epidemic during the summer. Lakah and Khouri noted in Alexandria that the Koch-Weeks epidemic appears before the gonococcal, the former attaining its maximum in June, the latter in September. Meyerhof verified these observations in Cairo and Upper Egypt, with the exception that he found the Koch-Weeks conjunctivitis to attain a primary acme in May or June and a second in September or October, the latter being concurrent with that of the gonococcal epidemic. In December the curve of incidence falls, and only sporadic cases occur until the first days of spring. This sequence is repeated yearly with astonishing regularity, though the epidemic varies from year to year in its virulence.

#### PECULIAR FEATURES OF CERTAIN EPIDEMICS.

##### *Gonococcal Conjunctivitis.*

We owe the main bulk of our knowledge of epidemic gonococcal conjunctivitis to the workers in Egypt, who have long recognized this variety of ophthalmia, and have studied its epidemiological features very carefully. Quite recently MacCallan and Beaton have drawn attention to the differences, long familiar to tropical practitioners, between gonococcal conjunctivitis as seen in Egypt and in some other tropical and subtropical countries, and the same disease—at least so far as origin is concerned—in Europe. Those differences may be briefly stated: (1) The tropical form usually results from contagion acquired from another conjunctiva instead of from the genital organs; (2) it is frequently subacute or chronic in its course; (3) it shows definite seasonal variations, becoming epidemic as the atmospheric temperature rises; (4) it is a far less virulent disease than that met with in Europe, the cornea often escaping injury. These observers are of opinion that the Egyptian disease is truly gonococcal, and that it is not due,

as has been suggested, to a different organism which morphologically resembles the gonococcus. Beaton is now engaged on a further study of the subject, and is preparing immune serums, with the object of throwing light on the specific vital characteristics of the Egyptian conjunctival organisms as compared with genital gonococci.

The same disease has been studied in Indo-China by Talbot, who has watched it spread in families, in limited areas, and in whole villages during the hot months of July, August, and September. He has attributed the diffusion of the disease to the carriage of infection from case to case by fingers and other soiled objects. Similar evidence has come from different parts of the world, and certainly one of the most interesting of these contributions is that which comes from Samoa. We know that about a century ago a form of purulent ophthalmia was prevalent in Samoa and other South Sea islands, and that it became epidemic "in the bread fruit or fly season." It is believed that its appearance in Samoa dates from contact with the Canaanian, and is therefore one of "the blessings of civilization," which have been such a curse to those islands. In any case we know that gonorrhoea was very prevalent throughout the South Sea islands at the close of the eighteenth century. More recently the epidemics of the disease, which has come to be known as Samoan conjunctivitis, have been milder in type and smaller numerically than they were formerly. The symptoms are those of gonorrhoeal ophthalmia, but in a distinctly modified form; the cornea and the uveal tissues may be severely affected in neglected cases, but in those submitted to suitable treatment serious complications are absent. Quite recently Hunt has investigated Samoan conjunctivitis bacteriologically and with the aid of cultures, and has found that it is due to a Gram-negative diplococcus which he believes to be a modified form of the gonococcus. Not the least interesting part of his investigation was the implantation of the virus of the disease on a healthy conjunctiva, on a healthy male urethra, and on a virgin vagina. Of the three subjects two were volunteers and one was a prisoner.

Enough has, I think, been written to show that this form of tropical conjunctivitis has very definite characteristics of its own, and that it merits the careful attention of all who would practise ophthalmology in the tropics.

##### *Membranous Conjunctivitis.*

A disease rare in Europe, membranous conjunctivitis is, of far more frequent occurrence in certain tropical countries, and may even occur there in epidemic form. Thus between September 7th and 20th, 1922, an epidemic of nineteen cases, all of which were truly diphtherial, was seen at Assiout (Girgis), whilst three more diphtherial cases and forty non-diphtherial appear in the same year's report. The ophthalmologists of Egypt regard the subject as so important that they recently went so far as to devote a special session of their annual meeting to its discussion (Ophthalmological Society of Egypt, *Bulletin* of 1923). MacCallan and Rasheed Bey there dealt with the bacteriological side of the question, and pointed out that organisms other than the diphtheria bacillus may produce a membranous conjunctivitis; their list included the staphylococcus, the streptococcus, the pneumococcus, the gonococcus, and the Koch-Weeks bacillus in addition to the Klebs-Loeffler organism. The non-diphtherial cases are rather less severe than the diphtherial.

Infection with Klebs-Loeffler bacillus may take place (1) directly by contact, or by fly transmission from case to case; (2) through a diphtheria carrier who presents no symptoms; (3) by such a carrier suffering from nasal catarrh; (4) through dust infected by dry membrane, etc.; and (5) by want of care in the handling of eyes in the out-patient department.

Other points of interest which were brought out at this meeting may be briefly alluded to. The affection may be unilateral or bilateral, and one eye may be much more strongly infected than the other. Diphtherial conjunctivitis is not often accompanied by faecal or nasal diphtheria in Egypt. Paresis of accommodation may occur as the result of a previously undiagnosed attack of ophthalmia (Sobhy of Bey), though such an event must apparently be regarded as

very rare; indeed, MacCallan and Rasheed Bey have never seen the accommodator muscle affected in any of their cases. All varieties of membranous conjunctivitis may be accompanied by glandular enlargement. When it occurs in epidemics true diphtherial conjunctivitis appears to pass from eye to eye, and it is rare to get a history of contact with patients suffering from the usual forms of diphtheria. Symblepharon is never seen after the disease in Egypt, but 63 per cent. of MacCallan and Rasheed Bey's cases had corneal ulceration, and 50 per cent. lost one or both eyes; this unfortunate record—so much worse than might have been anticipated from European experience—was largely due to the fact that diphtherial, like many other forms of tropical conjunctivitis, is often a mixed infection. When in doubt as to the cause of a membranous conjunctivitis a dose of antitoxin should always be given whilst waiting for the bacteriological report. Constant irrigations with encol and painting of the conjunctiva with 2 per cent. silver nitrate solution are recommended; when the lids are swollen hot fomentations should be used. Fly-proof rooms or tents are advocated, and careful disinfection should be carried out at the end of each case, for diphtherial membranes, when dry and kept in the dark, may produce cultures months afterwards. Those in contact with the cases are advised to gargle with potassium permanganate solution (1 in 5,000) thrice daily, and to wear protected glasses; utensils should be disinfected in buckets containing solution of cyllin (1 in 200), and the same disinfectant should be placed in convenient spittoons.

#### *Swimming Bath Conjunctivitis.*

Of late years attention has been directed in various centres in Europe to the occurrence of severe epidemics of conjunctivitis which have had their origin in swimming baths. In one at least of these, which occurred in Berlin, the bath was well cleaned and well built. The interest of these observations to the tropical ophthalmologist lies in the clear implication that the conjunctiva may be readily infected from contaminated water, and that we have here a possibly fruitful line of investigation in our study of the epidemics of conjunctivitis with which we are so familiar in the tropics. It may well be that under tropical conditions water, and especially dirty water, may at certain times of the year breed in abundance some at least of the forms of organism which are responsible for such epidemics. No one who has visited Turkish baths in an Eastern city, or who has watched Oriental natives performing their ablutions in polluted water, can fail to be suspicious of the possibility of this form of transmission of infection.

#### *Pediculous Conjunctivitis.*

Some years back Ruata recorded the observation that the eyelids of negroes are especially liable to attack by the public louse. More recently Blane has noticed a close connexion between pediculosis of the scalp and phlyctenular conjunctivitis both in France and in Tunis. It is of peculiar interest that the connexion between these two conditions in his tropical practice was equally marked both amongst Europeans and Arabs. He has had similar experiences also at Athens and in Crete. To confirm the connexion he injected into the eye of a monkey an emulsion of ground-up lice and produced a typical phlyctenular conjunctivitis a little over two months after the inoculation.

#### *Koch-Weeks Conjunctivitis.*

In lands where trachoma is rife, Koch-Weeks infection plays so important a part that prophylactic measures against it merit very careful study. Recently Nicolle, Conseil, and Cuénod have been studying the advantages of preventive inoculation against this form of conjunctivitis. Both subcutaneous and subconjunctival injections were employed, and the patients were then subjected to the instillation into the conjunctival sac of fresh cultivations of the Koch-Weeks bacillus without any serious symptoms supervening, whilst a control case showed typical infection. To those who know the havoc wrought in tropical countries amongst trachomatous patients by mixed infections—in which the Koch-Weeks organism plays a by no means unimportant part—these observations will have a very real importance.

## THE TREATMENT OF VARICOSE VEINS OF THE LEG BY INJECTIONS.

BY

JOHN DUNBAR, M.B. GLAS.,

ASSISTANT SURGEON, GLASGOW ROYAL INFIRMARY.

DURING my student days I became greatly interested in varicose veins of the leg, on account of the number of operations performed and the number of recurrences which I saw at the dispensary. It was evident to me then that there was no one operation which could with certainty be relied on to effect a cure, recurrences taking place after each of them in a large proportion of cases. This impression has been greatly deepened since, and has led me to try some other means of benefiting these patients without the necessity of incapacitating them for work for at least six weeks and without the risk of a general anaesthetic.

Dr. Sicard in 1923<sup>1</sup> described his method of injecting varicose veins with sodium salicylate. Thrombosis of the veins is produced. The danger of producing thrombosis in veins, to my mind, was the fear that the thrombosis would extend up the vein or produce embolism. Having had at that time (May, 1923) a large experience of treating haemorrhoids by injection, and also having convinced myself from clinical experience and the examination of microscopic slides that thrombosis was produced in these haemorrhoids, that the thrombosis did not extend up the vein, and that embolism was not produced, I commenced injecting veins with sodium salicylate, and have now treated thirty cases by injection.

My first patient was a female shop assistant with varicose veins of both legs. The left leg, being the worse, was injected. She was kept in hospital for one week after the injection, but was allowed to go about the wards. At the end of the week she was sent home. I have seen her at various intervals since, and on the last occasion she asked me to inject the other leg. She has never been off work since May, 1923, on account of the varicose veins, whilst previously she had to take days off repeatedly. The other cases have all been treated as out-patients and have not been incapacitated beyond one day, except one case in which cellulitis was produced.

The method employed by Dr. Sicard when using sodium salicylate is as follows: The susceptibility of the patient to the drug is tested by injecting about 1 c.cm. of 20 per cent. solution into the veins. If there is no reaction next day a stronger solution is used, but it is recommended not to go above 40 per cent. Several sections can be injected at the same time, but the total dose of sodium salicylate should not exceed 3 grams. No constricting band is used. The patient, as a rule, complains of a very severe pain coming on immediately after the injection and lasting about one minute. Occasionally goose-flesh feeling and slight cramp in the leg or foot are noticed, lasting for a short period. Dr. Sicard states that this method is very suitable for varicose veins which are bunched together, and that one injection may effect a cure. If a cure does not result the treatment can be repeated. Immediately following injection the vein swells, and its contents can be felt becoming hard. When examined about a week afterwards one or two things will be found if a cure is going to be effected: (1) a hard mass is felt in the vein at the seat of injection, and (2) in addition it is found in some cases that thrombosis is extending down the vein. In no case was extension up the vein noted. Later the vein, if thrombosis has extended downwards, becomes replaced by a fibrous cord. If thrombosis has only occurred at the seat of injection, the veins below remain patent and varicose, but whatever happens the patient always states that the veins are reduced in size and the strength of the limb is greatly increased. On account of the severe pain experienced after injecting sodium salicylate, I have been trying the effect of mercury perchloride (1 in 500). A few minims only are injected at different points. There is less pain, the swelling of the vein is much less, and the results are as good. My method is to insert into the vein a fine needle pointing downwards. When the blood flows freely through the needle I attach the syringe containing the fluid to be

injected, block the vein above the needle with my left thumb, and inject slowly into the vein. The syringe is then removed, and the blood prevented from flowing out of the needle by placing a finger on the mount. The needle is left *in situ* for about one minute, or until no blood flows out of it. The left thumb is removed at the same time as the needle is withdrawn. During the operation the patient is seated at a convenient height. By this method the fluid is prevented from getting into the cellular tissues. In one case, where some 30 per cent. solution of sodium salicylate got into the cellular tissues, cellulitis was produced and a slough formed at the site of injection. As the tissues over a varicose vein are very thin and their vitality greatly reduced, this is liable to happen unless great care is taken to ensure that no fluid escapes into the subcutaneous tissues. Where a varicose ulcer or eczema is present the effect of the injection is sometimes very marked.

In no circumstances would I recommend the injecting of an inflamed vein. In my opinion, before treatment is begun a considerable period should elapse after inflammation has been present, both on account of the danger of producing a recrudescence of the inflammation and subsequently septic emboli, and also, in some cases, after phlebitis it is found that a cure has resulted.

I do not claim that the results of injecting varicose veins are better than those obtained by operation, or that the liability to return of the varicose condition is less (in fact, I would expect the percentage of recurrences to be higher); but I do claim that the treatment improves the circulation in the legs, and consequently the strength of the lower extremities, without incapacitating the patient in any way.

## DORSO-LUMBAR DISLOCATION OF THE SPINE REDUCED BY OPERATION.

(With Special Plate.)

BY

W. A. H. MCKERROW, M.B., F.R.C.S.,  
HONORARY SURGEON, PRESTON ROYAL INFIRMARY.

THE occurrence of spinal dislocation without fracture is extremely rare below the cervical region. The case to be described was practically a pure dislocation of the twelfth dorsal from the first lumbar vertebra.

Walter R., aged 25, motor driver, was admitted on February 4th, 1924, to the Royal Infirmary, Preston, suffering from shock and paraplegia. The following history was obtained: When driving a heavy vehicle from Ormskirk to Preston, the same evening, he had stopped just round a right-angled bend in the road, and got underneath the car, taking the rear light with him, to inspect and repair a leaking petrol pipe. Another vehicle ran into the stationary car from behind, and knocked it forwards a few yards; one of the wheels passed over R.'s body.

On admission the patient was conscious and in a state of severe shock. There were numerous abrasions of skin over the chest and upper abdomen, especially on the right side. Both lower extremities were completely without power of movement; knee- and ankle-jerks were absent. There was no sensation in the right foot and reduced sensation in the other parts of the lower limbs. The patient complained of great pain in the back and at the right side of the chest; respiration was difficult. Subconjunctival haemorrhage was present in both eyes. There was swelling and loss of alignment of spinous processes at the dorso-lumbar region, without undue prominence of any particular spinous process. Sphincteric control was lost. The abdomen was soft, and resonant in the flanks. The tenth right rib was fractured.

X-ray examination on February 5th showed a lateral dislocation of the twelfth dorsal from the first lumbar vertebra, with displacement of the lower portion of the spine to the right. Apart from a small chip of bone detached from the left upper margin of the first lumbar body, the injury was a pure dislocation (see Fig. 1).

An attempt at reduction under anaesthesia on February 6th by traction, etc., was unsuccessful.

On February 7th, assisted by my colleague Mr. A. Toulmin, I exposed the injured part by a median dorsal incision, with the patient in the prone position. The articular processes were intact; the left lower articular process of the twelfth dorsal vertebra was placed externally to the left upper process of the first lumbar, thus opposing reduction. Laminectomy of the first lumbar was performed, but this did not help matters much, except to give a better view of the spinal cord, which was seen passing obliquely in a strap-like manner between the displaced vertebrae. The spine was then flexed at the injured part by raising the lumbar bridge of the

operating table. This disengaged the articular processes; by lateral pressure they were forced into correct alignment and the spine was then allowed to extend by letting the bridge down. The articular processes thereupon fell into their correct positions, and as they were intact there was no tendency to recurrence of the displacement (see Fig. 2). The dural sheath of the cord appeared to be uninjured. Muscles and fasciae were united as well as possible; a small drain was placed at the lower end of the wound.

After operation the patient was kept on his back, with a pillow under the injured part of the spine. There was complaint of pain and "pins and needles" in the legs for two days. Cystitis was present, the urine being alkaline and containing blood and pus. Regular catheterization was necessary.

On February 11th very slight active movements were elicited at the left great toe. Tested on February 21st, most of the muscles of both lower limbs were found to respond to faradism, the responses being weaker on the right side than on the left. Within three weeks there were feeble active movements in the muscles of both limbs, above and below the knee. Under treatment by massage and electrical stimulation these gradually became stronger. Sensation was normal, except at the right sole, where it was diminished, and over the right great trochanter, where it was absent over a small area (see later). A small bed sore over the sacrum appeared, but soon healed.

By March 10th the cystitis, in spite of the usual remedies, was alarming; the urine was very foul, and the patient was running a temperature of 100° to 101° every evening. There was a small hard swelling above the pubic symphysis. On March 20th a suprapubic incision was made and pus evacuated from an abscess behind the symphysis. A separation of the symphysis, wide enough to admit a finger, was found; this injury had hitherto escaped observation. The bladder was then opened and a tube inserted. Subsequently the patient's general condition improved markedly. The suprapubic incision eventually closed, after which catheterization was again necessary. There were no signs of returning control over the anal sphincter. The patient was discharged, to attend as out-patient, on September 18th. He had been trying his legs, assisted by crutches, occasionally during the previous three or four weeks.

Present condition (October 28th): The general condition is fairly good, and the patient maintains a cheerful outlook, as indeed he has done ever since the accident. He eats well; his weight is 8 st. 6 lb. (normally 9 st. 10 lb.). The operation wounds are well healed. He can get about the house without the aid of a stick; outside he can walk about half a mile with two sticks. He takes an aperient every three days, otherwise his bowels do not act. Having taken the aperient, he prepares to be incontinent. He wears a catheter, leading into a portable urinal. The catheter is removed and replaced twice weekly.

In walking the right leg is thrown outwards, as slight foot-drop is present. The left leg is a sound and useful limb, with full range of movement, active and passive; but the knee-jerk is weak and the ankle-jerk not elicited. The right leg is considerably weaker—for example, when sitting in a chair the patient can only partially extend the knee with the foot off the ground. Full passive extension of the knee is obtained, but not full flexion. The ankle is somewhat stiff and cannot be dorsiflexed passively to less than a right angle. The anterior and posterior tibial muscles have active power, but are weak; toe movements are almost absent. The peronei exhibit very faint active movements. The anterior part of the foot is somewhat inverted, giving a slight degree of pes cavus. No knee- or ankle-jerk is elicited on the right side, and the whole limb feels cold to the touch as compared with the left. There is slight oedema at both ankles and feet, more marked on the right side. Sensation to light touch with cotton-wool and to pin-prick is present over both lower extremities, except at a small area, about 4 inches square, over and above the right great trochanter, extending almost to the iliac crest. This area is quite anaesthetic to touch and pain; no doubt it indicates a laceration of the twelfth dorsal nerve, whose lateral cutaneous branch supplies this area. Although present, sensation is diminished at the right sole. Plantar reflex is not obtained at the right foot; at the left the second to fifth toes extend slightly, and the great toe remains motionless.

The right thigh measures 2 inches less than the left in circumference at middle; the right calf is half an inch less than the left. Oedema of the right calf masks the wasting of muscles. The muscles of the left leg respond to faradism, including the intrinsic muscles of the foot. On the right side response is feebler and absent from the peronei and foot muscles.

The urine is alkaline and deposits pus and phosphates; specific gravity 1020; albumin present. Treatment is being continued. (There has been some improvement in the condition of the urine since this report was written, and it is hoped soon to dispense with the catheter.)

#### Comments.

The spinal cord being crushed at the lower part of the lumbar enlargement—where the centres for control of the bladder and rectum are situated—recovery of voluntary control of these was not to be expected. Most of the nerve fibres to the muscles of the lower extremities have left the cord above the level of the injury in question, and in this case they soon began to recover from the pressure to which they had been subjected. A laceration of the twelfth dorsal nerve, at its exit from the intervertebral foramen between the twelfth dorsal and first lumbar vertebrae, is readily conceivable, to account for the area of anaesthesia over the great trochanter on the right side.

Most authorities are agreed that operation is rarely indicated in cases of spinal injury with complete transverse lesion of the cord, unless the injury is below the first lumbar vertebra. One would not go so far as to extend this limit upwards by a vertebra, as a general rule, on the strength of the case described; for although early and complete reduction was obtained, the patient is still, and is likely to remain, very much of an invalid; inasmuch as a return of sphincteric control is not to be expected. The presence of cystitis, moreover, which persists to some degree in spite of treatment, is a constant menace to the integrity of his kidneys. Nevertheless, the measure of recovery which has taken place is very encouraging. It is largely to be attributed to the optimistic outlook of the patient, and the skill with which he has been nursed.

The chief point of interest is the extreme rarity of such a lesion. Dislocations of the spine without fracture occur almost entirely in the cervical region—about 98 per cent. The remainder occur in the dorsal region. I have not been able to find any previous record of a dorso-lumbar dislocation.

I am indebted to Dr. A. Rayner, honorary radiologist to the Infirmary, for the excellent radiographs.

### A CASE OF

## SUPRARENAL TUMOUR, WITH DEGENERATION OF THE RETICULO-ENDOTHELIAL SYSTEM.

(With Special Plate.)

BY

J. GRAHAM WILLMORE, AND MACKENZIE DOUGLAS,  
M.D., M.R.C.P., M.A., M.D.

IN a leading article in the *BRITISH MEDICAL JOURNAL* of September 20th, 1924, the question is raised as to what might occur in the event of damage to the cells of the reticulo-endothelial system. Comment is made as to the lack of clinical evidence on this subject, and the need for further investigation regarding the effects on digestion and metabolism of a diminished formation of bile.

A case recently under the care of one of us may possibly supply the answers to at least some of the problems thus postulated, and we think that a fairly full report of it may be of scientific interest.

X. Y. Z., aged 31, first seen on April 22nd, 1924, complained of diarrhoea and vomiting. The date of onset was uncertain, but probably not earlier than July, 1923. He had served in France, Salonika, and with the Egyptian Expeditionary Force from 1915 to 1919. He had "enteric" in 1916, but no other serious illness. Family history unimportant. Height 5 ft. 5½ in.; weight 8 st. 4 lb. 4 oz. On admission he was pale, and his general condition poor. His tongue was raw and red, with (later) small, sore, sprue-like ulcers on its right lateral surface near the tip. The teeth were in order. There was no pigmentation of skin, and no icterus. The central nervous system was normal, but he stammered.

The abdomen was distended, tympanitic, and rigid. There was tenderness in the right hypochondrium, where the patient complained of constant severe pain during the whole of his illness. No mass was palpable (confirmed by several observers).

The liver was diminished in size (percussion and x rays). No abnormality was detected in the spleen, heart, or lungs.

The urine was acid; specific gravity 1010; there was a faint trace of albumin; no sugar. (N.B.—Glycosuria had been found previous to admission.) No acetone or diacetic acid was present. Diastase: 23–25 = 20 units—that is, within normal limits. Microscopically, hyaline casts and polymorphonuclear cells were found. Cannidge's reaction was positive.

The blood Wassermann reaction was negative on repeated examination, both before and after provocative neosalvarsan. Blood pressure 190/130. A blood count showed: red cells 5,530,000; haemoglobin 80 per cent.; colour index 0.7; white cells 15,500—polymorphonuclears 64 per cent., eosinophils 1 per cent., large mononuclears 4 per cent., lymphocytes 31 per cent.; no abnormal cells were present. (On August 8th the red cells numbered 6,000,000; haemoglobin 80 per cent.; white cells 22,700—polymorphonuclears 70 per cent., eosinophils 1 per cent., large mononuclears 9 per cent., lymphocytes 20 per cent.) Urea, 0.015 per cent.; cholesterol, 0.145 per cent. Van den Bergh's test showed no direct reaction, but a very weak positive indirect (mere trace).

Blood sugar:

(a) 9.30 a.m. (fasting) 0.081 per cent.	
(9.35 " 50 grams of glucose per os.)	
10.5 " 0.155 per cent. ... ..	(Urine, 0)
10.25 " 0.225 " ... ..	{ " 2 per cent. }
11.5 " 0.187 " ... ..	{ " 1.51 " }
11.35 " 0.175 " ... ..	{ " 0 }

(b) 10.27 a.m. (fasting) 0.118 per cent.	
(10.30 " 50 grams of lactulose per os.)	
11.0 " 0.150 per cent. ... ..	{ Urine, 0 }
11.30 " 0.143 " ... ..	{ " 0 }
12 noon 0.131 " ... ..	{ " 0 }
12.30 p.m. 0.085 " ... ..	{ " 0 }

The faeces were abundant, pulsatious, light clay coloured, fermenting, and offensive; they were completely acholic by chemical examination.

Neutral fat ... ..	16.8 per cent. = 25.5 per cent. of all fat
Fatty acid ... ..	38.5 " = 58.6 " "
Soaps ... ..	10.5 " = 15.9 " "

Total ... 65.8 per cent.

N.B.—Total should not exceed 22.5 per cent.

Microscopically, muscle fibres, oil globules, and fatty acid crystals were found in the faeces. There were no protozoa, cellular exudate, blood, or mucus; no tubercle bacilli were found. The benzidine test showed no occult blood (on meat-free diet).

Sigmoidoscopy revealed no abnormality.

The fractional analysis of a test breakfast (oatmeal gruel) revealed no free hydrochloric acid, and a total acidity not exceeding 0.018 per cent. During an attack of vomiting, however, on May 15th, the vomitus showed 4.9 per cent. of lactic acid, with no free hydrochloric acid. An opaque meal revealed a high active stomach, with a normally acting intestine, empty in twenty-four hours.

No gall stones were found on a special examination. Loewi's mydriasis test was negative. The temperature was afebrile, and the pulse between 74 and 96.

On the presumption that the illness might be due to sprue of an unusual type, the patient was put to bed on a sprue diet (fat-free) and given calcium lactate gr. xx t.i.d.s. and parathyroid gr. 1/10 t.d.s. The only effect of this was to convert the diarrhoea into a most obstinate constipation—not relieved by *fel hovin*, gr. xv t.d.s.—which lasted until the patient's death, long after the sprue treatment had been discontinued. At no time (except when bile was being administered) did the stools show a trace of bile in any form, at no time was there any evidence of jaundice in skin, conjunctivae, or blood serum, nor did the urine show a sign of bile pigments or salts. On the supposition that the case might be due to syphilis a course of intravenous neosalvarsan (two injections of 0.15 gram at weekly intervals) was begun; but this provoked such intense headache, with albuminuria up to 1.7 grams per litre, that it was abandoned.

The patient's progress thereafter was steadily downhill, the liver began to increase in size, and his weight fell to 7 st. 10 lb. 8 oz. On August 8th he developed a lobar pneumonia which was practically afebrile throughout, the temperature rising to 100° F. during three days of the first week only. The respirations, on the other hand, rose to 56 and the pulse to 120. He died on September 2nd.

### Post-mortem Examination.

At the autopsy, sixteen hours after death, *post-mortem* rigidity was present. The body was emaciated. There was no sign of jaundice in the skin.

**Thorax.**—There were no adhesions and no fluid in either pleura. The lining of the trachea and large bronchi was hyperaemic, and there was much viscid muco-purulent material. There was consolidation of both lobes of the left lung and of part of the lower lobe of the right lung. There was no sign of tuberculosis and no new growth. The heart weighed 13½ oz. There was some hypertrophy of the muscle walls, which were soft. There was no change in the valves. There was no atheroma of the coronary arteries. There was some fatty change in the first part of the aorta.

**Abdomen.**—The stomach and duodenum showed no change of note. In the small and large intestines there were patches of hyperaemia but no other change of note. There was no evidence of dysentery. The pancreas, which weighed 1½ oz., showed no naked-eye change. Attached to the tail by adhesions was a tumour about the size of a man's fist. This tumour, lying above the upper pole of the left kidney, was attached by adhesions to the spleen and to the transverse colon. The spleen was very firmly attached, and could only be separated by tearing away some of the splenic tissue. The left suprarenal could be definitely seen to be embedded in the tumour, characteristic suprarenal tissue being seen at the lower portion of the tumour. On the surface the tumour was nodular and on section it had a patchy yellow and dark red appearance with many cysts, some of which had well marked fibrous walls. The largest cyst was about 2½ inches in diameter. Most of the cysts contained a dark brown "colloid" material, but the contents of the large cyst were of a slightly more fluid consistence. The right suprarenal showed no new growth or change of note. Along the left suprarenal vein were small new growths similar in appearance to the large one, but not cystic. The vein was greatly dilated and one of the growths with a diameter of three-eighths of an inch had budded into the vein and was attached to the intima. It did not occlude it, however. The kidneys showed little change of note to the naked eye, except slight enlargement of the left. The capsules stripped readily. There were no new growths in either. The right weighed 5½ oz. and the left 7½ oz. The liver was slightly enlarged. It weighed 3 lb. 13 oz. The change in appearance was very striking, looking like a very marked "nutmeg liver," the dark patches contrasting very markedly with the light fatty portions. There were no new growths present in the liver, and there was no indication of any abscess and no scarring. The gall bladder contained a little yellowish mucus.

Microscopic examination of the tumour showed at one portion the normal cortical portion of the suprarenal with practically no medulla; the tumour seemed to grow from one portion of the zona fasciculata, the cells near the suprarenal being in long pillars with increased fibrous tissue between the different acini. The cells had the appearance of polygonal epithelial cells, like liver cells,

characteristic of the middle zone of the suprarenal cortex. Further away the cells were arranged in round masses separated in places by a delicate stroma and wide capillaries filled with red blood corpuscles. At other parts of the tumour there was much fibrous tissue, and at places the tumour was undergoing mucoid degeneration with disappearance of the alveoli; at places it would appear that the cystic appearance was due to these degenerated areas surrounded by the thick fibrous tissue with haemorrhages. At one point there was much pigmentation and fibrous tissue as from an old haemorrhage. The bud growing in the vein showed round masses of cells similar to those in the large tumour. There was not much interstitial fibrous tissue in this growth, but the cell masses were separated by capillaries which were congested. Mitotic figures were not frequent and seemed to be fairly regular. The nuclei of most of the tumour cells contained well marked round nucleoli. (See Figs. 1 and 2 on Special Plate.)

The suprarenal of the right side showed microscopically little change of note.

The pancreas from the portion adjacent to the tumour showed the islets of Langerhans slightly disintegrated, the strand-like appearance of the cells being lost and the protoplasm of the cells diminished. There was little change in the nuclei of the cells and the alveoli of the pancreas were fairly well preserved. There was no invasion of the organ with new growth.

The spleen showed some fibrosis, and at places, especially where it was adjacent to the tumour, there was necrosis. At other places the organ looked oedematous and to have lost the arrangement of pulp sinuses.

The liver showed very advanced fatty change. In a paraffin section there were places where the appearance was that of adipose tissue with the large clear spaces from which the fat droplets had been dissolved. There was very little cells, but the cell nuclei showed up well.

system seemed to be quite obliterated. of the peripheral and middle zone of the lobules. Round the central venule the degeneration was even more marked. There were no liver cells intact. There were only red cells, polymorphs, some nuclei, and dark brown pigment globules. The pigment did not give a blue reaction with potassium ferrocyanide and hydro-

chloric acid, but remained dark brown. Frozen sections stained with haematoxylin and Schiarlach R showed the adipose appearance very markedly, the large fat droplets quite obliterating the protoplasm of the liver cells, while round the central veins were the red cells and dark brown pigment granules. Sections stained by Langhans's method showed complete absence of glycogen.

The two remarkable findings at the autopsy were: (1) The occurrence of a true tumour of the suprarenal in contradistinction to the hypernephroma which are usually found to arise in the kidney. Budding of the tumour occurred to a slight degree in the neighbourhood of the tumour, but there were no metastases. (2) The fatty changes in the liver and the central degeneration of the lobules were as marked as those after chloroform poisoning, and greater than in any other condition in our experience.

### Conclusions.

The clinical condition of the patient, the constant pain in the right hypochondrium—which at times was so severe as to suggest biliary colic—and the nature of the stools, all pointed to the liver being the primary seat of the disease; the site and comparatively small size of the tumour, the rigidity of the distended abdominal walls, and the fact that the patient never complained of pain or tenderness on the left side, all combined to mask the presence of the tumour.

We hazard the suggestion that from the first some poison must have been at work—possibly one secreted by the neoplasm—with a special selective action upon the hepatic parenchyma, and, to a less degree, on the spleen. The result of this was that the hepatic functions were almost suspended, the carbohydrate metabolism was disturbed, and possibly the haemolytic functions of the spleen were moderated; otherwise one would have expected at least some secondary anaemia in a man profoundly ill and cachectic for so long a period before his death.

## PERFORATION OF THE KIDNEY BY A LARGE BRANCHED CALCULUS.

PERINEPHRIC ABSCESS: SEPTICAEMIA: DEATH.

(With Special Plate.)

BY

WILLIAM EVERETT, M.B., F.R.C.S.ED.,

SURGEON, BARRY HOSPITAL.

It is well known that a large stone may rest in the kidney pelvis for many years with an almost total absence of any symptoms. The following case illustrates this very well, and I think it worthy of recording because of the unusual size of a branched phosphatic stone removed from the right kidney and of the clearly defused and interesting conditions found at the operation.

### History.

Mrs. K. M., aged 60, was admitted to hospital on September 26th, 1924, complaining of great pain across the back and over the right lumbar and hypogastric regions, accompanied by vomiting and diarrhoea. She stated that until six days previous to her admission she had been a very healthy woman, with hardly a day's illness in her life of sixty years. She had, however, suffered from time to time from bouts of flatulence, and when this occurred she had a dull aching pain in the back which disappeared after getting rid of the flatulence. A point, to which I at first did not pay much attention, but which might have an important bearing upon her illness, was that six weeks previous to the commencement of her illness she complained of a severe pain in her back after lifting a heavy bucket of water. On September 20th, she complained of general backache on getting up in the morning, which later in the day became more severe and settled down to the right of the spine. She felt ill and that night had a rigor and vomited. Vomiting occurred several times daily from the commencement of her illness. On the third day she complained of the pain spreading round to the front of the abdomen on the right side. On the fifth day she again had a rigor and diarrhoea began. The pain remained severe and gave her no rest that night. She called in Dr. Irving of Barry on the morning of the sixth day, who advised her removal to hospital. Careful investigation of her past life revealed no history of any haematuria, no colic or radiating pains, no frequency of micturition, and her water as far as she knew had always been clear. As stated above, there had been occasional dull lumbar pain associated with flatulence.

### Examination.

The face was flushed, with marked pallor round the mouth, the tongue was furred and dry, and the breath was foul. Her temperature was 99.8°, the pulse 128 and of little volume. Her picture was that of general toxæmia. She was a big, well built woman. On examination of the abdomen there was a visible swelling of the right hypogastrium. On palpation a rounded, tender swelling the size of a large coco-nut, dull to percussion, could be felt filling the right hypogastrium, extending forward to the middle line and down into the right iliac fossa as far as the middle of Poupart's ligament, but here its lower border was ill

defined and the fingers could not get below the tumour. The swelling could be pushed forward slightly with a hand placed posteriorly. In the absence of urinary symptoms the diagnosis was obscure, although it was thought that the swelling was renal in origin. The urine showed only a trace of pus, with no sign of blood.

### Operation.

A general anaesthetic was administered by Dr. Neilson of Barry, and the abdomen opened in the region of the right semi-lunar line. Examination revealed a large kidney, bigger than a coco-nut, with a boggy fluctuating swelling below its lower pole extending to the brim of the pelvis. The peritoneum was again drawn together and was peeled off the anterior surface of the kidney, the ascending colon and caecum being displaced inwards and packed off with towels. A large, very foul abscess, smelling of *B. coli*, and of the consistency of thick cream, was opened into. There was oedema and induration of the surrounding cellular tissue and fat. The abscess, which was outside the fatty capsule of the kidney, and which extended inwards and downwards to the brim of the pelvis, was first of all swabbed up. The fatty capsule was greatly indurated, and on piercing it with the finger several ounces of urine and thin pus were evacuated. On palpating the enormous kidney, a hard body, presumably stone, could be felt in the upper pole. At the lower pole the finger encountered a soft necrotic area, about the size of a florin, through which a stone could easily be felt. The kidney was so indurated that the body of the large stone which was subsequently removed was not felt on palpation. In view of the critical condition of the patient, and of the superadded difficulties that would be met in removing such a kidney, it was decided to remove the stone by splitting the kidney in its long axis. Although it was found impossible to put a clamp upon the pedicle without grave danger to the major vessels, because of the matting and induration of the fat in the hilum, the kidney did not bleed much on section. The kidney substance was very indurated and grasped the stone firmly. Three of the dendritic processes broke from the body, and one was removed through the perforation in the lower pole. After extraction of the fragments the kidney was sutured in the usual manner. Ample drainage was provided, and intravenous and subcutaneous salines were administered before the patient left the theatre. She came out of her shock, but died on the evening of the third day following the operation, from septicaemia. A post-mortem examination was not obtained.

### Pathology.

The accompanying sketch illustrates the interesting conditions found at the operation and suggests the pathological sequence: (1) Stone formation. (2) Infection and necrosis of kidney substance

in contact with dendritic process A. It is conceivable that with a stone of this weight and size a sudden jolt, such as may have taken place on lifting a heavy bucket of water six weeks previously, may have caused the dendrite A, which was sharper and more dependent than the others, to tear the lining of the calyx into which it fitted, and thus to have made an entrance for bacterial infection of the kidney substance. (3) Perforation of the kidney with leakage of urine and formation of abscess within the fatty capsule. (4) Extravasation beyond the fatty capsule with abscess formation and cellulitis of the posterior abdominal wall. (5) Septicaemia.

The photograph (see special plate) is a reduction of one showing the actual size of the stone. Its measurements are as follows: length  $4\frac{1}{2}$  in., girth 3 in., circumference  $12\frac{1}{2}$  in., weight 1,202 grains (24 oz.). It consists of calcium phosphate.

#### Remarks.

It is instructive to recall with the pathological findings the history and the clinical picture. The total absence of any symptoms, excepting bouts of flatulence, although the stone must have been there for many years; the more acute onset of pain and rigor, corresponding with the invasion of the kidney substance by organisms, and final perforation brought about by the continual pressure of a heavy stone upon an infected and necrosing area; the extension of pain in the back to the anterior abdomen following the spread of infection in the perinephric and iliac cellular tissues; the symptoms of profound toxæmia, especially the vomiting and diarrhoea.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### A CASE OF MEASLES WITH MENINGISM AND SURGICAL EMPHYSEMA.

The following case of measles, occurring in a child aged 2½, the daughter of a marine stationed at the Depot, Royal Marines, Deal, seems to be worth recording on account of its unusual complications.

After coryza and general malaise for about four days the child became covered with a typical and extremely well marked measles rash; Koplik's spots were present on the gums; the temperature was 102° F., there was slight tonsillar enlargement, and sibilant bronchi were scattered over both lungs. On the following day there was practically no change in the child's condition or in the physical signs, but by the third day her state had become much worse. The temperature was 104°, the respirations 70, and well marked patches of bronchopneumonia were present in both lungs. Persistent cough was present, with considerable cyanosis, and symptoms of acute laryngitis were rapidly becoming manifest. Owing to the length of time before the result of a bacteriological examination could be obtained, and in view of the possibility of the laryngitis being diphtheritic, 4,000 units of antitoxin were given at once. Within a few hours there was a distinct improvement in the child's general condition, the temperature had dropped to 99.4° F., and the laryngitis had much improved. The lung condition was unaltered, however, and dyspnoea was still severe.

About this time a general puffiness of the skin of the neck was noticed, which rapidly extended up to the cheeks. On palpation crackling was readily elicited, and suggested surgical emphysema. During the next few days the condition became progressively aggravated until there was marked oedema over the head, neck, chest, abdomen, back, and upper extremities, the skin being raised from half an inch to an inch from the subcutaneous tissues. The patient's condition remained unchanged during the two following days, the temperature fluctuating between 100° and 103° F. The next day I was informed by the parents that the child had been extremely restless all night, and was apparently in great pain. I found marked retraction of the head and neck, with intense photophobia and opisthotonos. On being touched anywhere in the region of the skull the child uttered the piercing, high-pitched meningeal cry. Kernig's sign was strongly marked, no knee-jerks could be elicited, and there was no response to plantar stimulation. The child was semi-conscious, the respirations were 70, and the pulse was practically imperceptible. I decided to perform a lumbar puncture, and the same afternoon withdrew about 15 c.cm. of cerebro-spinal fluid. This was under increased pressure, and was slightly turbid. It was forwarded to a pathological laboratory for examination.

The withdrawal of this fluid had an almost immediate effect; by the same night the patient's condition had definitely improved, full consciousness had returned, and she was able to recognize her parents. The pain appeared much less, and the child did not resent handling. Plantar stimulation was followed by attempted withdrawal of the foot. By the next morning nearly all the meningeal symptoms had disappeared, and the temperature had dropped to 99° F. From this time on the patient rapidly improved and the lung condition began to subside. Within four days the temperature became normal, and the respirations had dropped to 24. The

child is now convalescent and doing well, though slightly irritable in temper. No organisms were recovered from the cerebro-spinal fluid, and a swab from the tonsils was negative for the Klebs-Loeffler bacillus.

With regard to the meningitis, a similar case is reported by Fien<sup>1</sup> in a girl aged 16, but in this case the cerebro-spinal fluid showed no turbidity. I have no explanation of the emphysema to offer, and can only submit the hypothesis that rupture of some air vesicles occurred through constant coughing, permitting air to escape via the anterior mediastinum to the subcutaneous tissues.

I am indebted to the Medical Director-General of the Royal Navy for permission to publish the details of this case.

Royal Marine Infirmary,  
Deal.

Surgeon Lieutenant-Commander, R.N.

### CONGENITAL MALFORMATION OF THE DIAPHRAGM.

THE following case illustrates what is, I believe, a very rare condition, and therefore seems to be worthy of record. I recently performed a necropsy on a male infant 11 days old. Its weight at birth was 4 lb. The parents were young and healthy. The child was apparently well nourished; it had been breast-fed and was slowly gaining weight. It had not been examined by a medical practitioner. I found the right lung normal and the heart in the middle of the chest; the left side of the chest contained about half a pint of clear fluid and the left lung was undeveloped. There was a large bulge of about 18 in. of the transverse colon into the lower part of the left side of the chest, above the diaphragm, and pressing against the heart. Several coils of the small intestine were also situated in the chest behind the colon. I found a large, well defined opening in the diaphragm behind the spleen and just in front of the left kidney; it admitted four fingers. There was apparently no strangulation, since the intestines moved freely in and out of the chest through the opening.

Stonehouse, Gloucestershire.

### TREATMENT OF PSORIASIS BY PARATHYROID EXTRACT.

IN THE BRITISH MEDICAL JOURNAL of April 26th, 1924 (p. 772), there was a note by Dr. Claude Wilson on the treatment of psoriasis by parathyroid extract. I was particularly interested as I have a patient, a man aged 40, who has suffered from psoriasis since the age of 8 years. Various forms of treatment have been used without success. Chlorsarobin, however, has never been tried, owing to the fact that the patient is unable to spare the time from his professional duties. He has noticed that from October to March in each year he is more or less free from the condition; whereas from April to September it is always with him.

Treatment by parathyroid extract was commenced on May 1st and continued until the end of August. The dose was 1/10 grain daily. I regret to say that there was no amelioration in the condition. There was no decrease in the number of lesions, which became redder and more irritable. Large crusts formed on the scalp to a much greater extent than ever before.

I am not suggesting that the disease was aggravated by the treatment, but I could not help feeling disappointed in view of Dr. Wilson's optimistic note.

Holt, Norfolk.

### OVARIAN CYST COMPLICATING LABOUR.

A good many years ago I saw in consultation a primipara who, some days before, had been delivered after a difficult forceps operation. When I saw her the abdomen was distended and she was obviously very ill. The perineum was ruptured into the rectum, from which hung the septic remains of an ovarian cyst wall. The fingers in the vagina passed straight into the abdomen, among the bowels behind the uterus.

I opened the abdomen at once, removed the remains of the cyst, and drained both through the abdominal wall and vagina, after repairing the rent in the recto-vaginal

<sup>1</sup> *Gaz. degli Osped.*, 1923, 464.

septum. The patient rallied from the operation, but died some days later from septic peritonitis.

This case, like that reported by Dr. Gordon Taylor in your issue of December 6th, 1924, emphasizes the necessity of ascertaining the cause of delay before resorting to forceps. With an anesthetized patient one may easily invoke the catastrophe of Dr. Gordon Taylor's and my own case.

Penrhyn Bay, Llandudno.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### CAMBRIDGE AND HUNTINGDON BRANCH.

##### AN APPARENT CASE OF HOUR-GLASS STOMACH.

At a combined meeting of the Cambridge Medical Society and the Cambridge and Huntingdon Branch of the British Medical Association, held at Addenbrooke's Hospital on December 5th, 1924, the following notes on a case of apparent hour-glass stomach were contributed by the President, Dr. J. R. GARROOD.

The congenital form of hour-glass stomach, which this case resembles, is referred to in the textbooks, but on examining the literature it appears to be a vanishing condition, due, I think, to more accurate diagnosis.

Saake (1896),<sup>1</sup> in the case of a female aged 67, states that the hour-glass contraction was obviously of congenital origin, while in the pyloric portion a large cancerous growth was discovered.

Rokitanski (1859)<sup>2</sup> mentions rare congenital malformations in which an annular contraction divides the stomach into a cardiac and pyloric portion or into three or four sacculated divisions.

C. F. Martin (1908)<sup>3</sup> thinks that in the specimen in McGill Museum from an infant the condition is so marked as to leave no room for any conclusion but that it is congenital; but, speaking of pylorospasm, he states that fixation in the contracted condition may take place at death in one phase of digestion.

Adami and McCrae (1914)<sup>4</sup> mention occasional cases of congenital hypertrophy of the mid zone of muscle, but Moynihan denies the existence of the condition.

The specimen here described was taken from the body of a male child which lived seven weeks. The mother was 47 years old; the labour was uncomplicated. The patient was the eighth child (the other children are normal); he weighed 7 lb. at birth and was breast-fed; he cried a good deal and vomited from the first; no treatment benefited him. The amount of vomit was estimated to be about as much as he took; it was yellow or brown; he also brought up wind which was offensive.

After the meconium but little faeces was passed, and that which came was described as looking like a worm; not much urine was passed. The upper abdomen was rather swollen. The patient wasted and died in seven weeks. On opening the abdomen a reversed S(2) shaped organ appeared, and apparently consisted of a double stomach. The upper and right limb of the 2 was directed backwards, its plane being nearly at right angles to the lower curve.

I removed the stomach and intestines, and wish now I had taken the liver and pancreas as well. On opening the organ both cavities were found to contain milk. The opening between the two admitted a wooden match. The cavities were of about the same size, and I thought I had a perfectly good hour-glass stomach. I removed a small piece of tissue from the junction piece, sections from which were examined under the microscope.

On further consideration I have come to the conclusion that the second sac is really the first and second parts of the duodenum, for the entrance to the common bile duct is found in it. The microscopic structure at the point of junction of the two sacs is similar to that at the pylorus, as is the macroscopic appearance, while the lower end of the second sac has no resemblance to it. If this is so, we have a dilated and hypertrophied duodenum brought about by an almost complete occlusion just below the entrance of the bile duct. This could not have been complete, for the infant lived seven weeks, but was very nearly so, as the patient starved to death, and the intestines are nearly empty; presumably seven weeks, even under bad conditions of nourishment, was sufficient time for the enlargement to take place.

In Green's *Encyclopedia*<sup>5</sup> it is stated that duodenal occlusion

occurs just above the entrance to the bile duct, and is due either to a membranous or to gradual narrowing. The vomit is not bile-stained, the bowels act several times after birth, and death occurs in one to eleven days. Obviously the occlusion in my case does not quite correspond with this account.

The specimen shows a stomach 14 cm. along its greatest curvature, with walls from 2 to 3 mm. thick, and, I believe, a normal pylorus—at all events it was patent, and the second cavity contained milk. This is followed by a sac 8.5 cm. along its greatest curvature, with walls of the same thickness as the stomach. They show plicae circulares within, and there is no mesentery; a bristle has been passed through a short piece of the portal vein behind. At the intestinal end of this sac is a transverse partition, and on the upper surface of this is a small opening, which on passing a bristle is found to lead to a vessel which I believe to be the common bile duct. The first part of the duct passes in the wall of the septum, and was so thin that it broke away, but the track can be seen in its substance beneath the bristle. A narrow opening can be made out in the septum near the posterior and inner wall. The intestine which immediately succeeds this partition appears quite normal. The sections show the thickened portion at the pylorus followed by the thinner first part of the second sac or duodenum. There is a gradual transition from pyloric glands to Brunner's glands and villi; the difference between these is never very marked, and I suppose would be even less obvious in an infant.

## Reports of Societies.

### RHEUMATOID ARTHRITIS.

At meetings of the Royal Medico-Chirurgical Society of Glasgow on December 5th and 12th, 1924, the President, Professor ARCHIBALD YOUNG, in the chair, a discussion was held on rheumatoid arthritis.

Professor R. STROCKMAN described rheumatoid arthritis as being probably a group of closely allied microbial diseases, such as chronic articular rheumatism, chronic rheumatic arthritis, chronic fibrous rheumatism, chronic villous polyarthritis, nodose rheumatism, rheumatic gout, atrophic arthritis, Still's disease, and chronic infectious arthritis. The clinical course and morbid anatomy marked it as a bacterial infection of low virulence, but of extreme chronicity. As a rule, no organism could be found in the areas affected or in the blood, but in a very small number of cases bacilli, diplobacilli, cocci, diplococci, and streptococci had been isolated from the joints. There were probably several different causal organisms, and this belief was supported by the considerable clinical and anatomical differences in individual cases. Whether all cases were due to the same organism or to various different organisms the broad results for the patient were the same. The white fibrous tissues of the locomotory system of the body were the sites of attack, and essentially and in the beginning the disease was a fibrositis, with proliferation and increase of the affected fibrous tissue structures. There was never any suppuration or local emigration of polymorphous leucocytes. Chronic hydrarthrosis of one joint was probably its mildest form, and from this there were all grades of severity up to polyarthritis with high fever. The disease usually began insidiously in the small joints and progressed with little constitutional disturbance; less often it began in the large joints with more acute systemic symptoms. Ultimately in all cases it presented the general clinical aspect of a low chronic septic infection. It must be regarded as a very general infection and not merely as an arthritis. In all cases the fibrous tissue of the muscle, aponeuroses, fasciae, and panniculus adiposus were more or less deeply involved and inflamed. In the joints the fibrous tissue of the synovial membrane and capsulae were primarily affected. The cartilage and bone were not primarily involved, but as the influence of disuse, muscular contractures, and other changes came into play the bone became thinned and atrophied, the cartilage rough or ulcerated, the fibrous capsule contracted and hardened, and ultimately a fibrous or a bony ankylosis might result.

The focus of infection could only very rarely be identified with certainty. It was possible that in many cases the original focus had disappeared before the patient came under observation, and one joint might remain as a reservoir

of infection after others had ceased to show active signs. Tonsillitis, boils, septic sores, pyorrhea, chronic pulmonary or intestinal conditions, and so on, had been blamed, and the association of various skin conditions, such as psoriasis, had been noted. The various methods of treatment, both local and general, were then described. In speaking of the protein shock treatment, Professor Stockman believed that in most early cases the method was capable of cutting short the infection. The later symptoms and changes which followed as a result of the fibrositis were referred to, and the necessity for vigorous treatment by massage, movements, baths, and appropriate exercises was urged—anything rather than rest. Treatment must be directed (1) to restore movement in the joints by elongating the contracted muscles and shortening the elongated ones so that they might regain their normal action; (2) to get rid of the fibrositis in and around the joints, and to stretch and render more pliable their ligamentous tissues and adhesions; and (3) to increase the bulk and strength of the muscles. For the most part the stretching and movements could be done manually, but the assistance of splints was desirable in many cases. Forceful extension under an anaesthetic was to be avoided, but in certain instances the mobility or otherwise of a joint could be more easily tested under chloroform. The fixation of a joint in plaster or splints for more than a few days was very inadvisable owing to the risk of immobility occurring.

Dr. DAVID CAMPBELL related the results of the treatment of rheumatoid arthritis, and described the technique he had employed in the treatment of 100 cases from 1921 to the present date. Of 70 cases treated up to November, 1923, 58 derived great benefit, both directly from diminution of pain and tenderness in the joints, and also indirectly from the consequent greater facility with which more effective local treatment by heat and massage could be carried out. The maximum benefit was obtained in those cases which had started acutely and with involvement of many joints. Of the 12 cases which showed no improvement, 4 were of long standing in which the disease process had become inactive. Seven patients reacted to each injection, but the infection remained active. Of the 50 patients improved by the treatment, 40 had, during periods varying from one to three and a half years, been able to perform all their ordinary duties, with no exacerbation of the joint conditions or spread of the disease to other joints. In 16 cases in which relapse had taken place a fairly advanced stage of the disease had been reached before treatment was started, while in several the treatment had been discontinued after two or three injections, owing to the great improvement shown. The advisability was considered of continuing the injections after the active process had apparently ceased. In conclusion, Dr. Campbell expressed the opinion that, while protein shock therapy could not be regarded as ideal, it offered greater probability of success than any other known methods.

Mr. JAMES RUSSELL, discussing the surgical treatment of arthritic conditions, referred to the various deformities which might result from these diseases. He strongly deprecated operative treatment based on x-ray appearances alone, and insisted that surgical interference could be justified only where improved functional value of the limb was likely to be attained thereby. The fundamental question was function, and mere deformity as such should not be allowed to assume undue importance. The commoner deformities of the various joints were then described and the methods employed for their prevention discussed. Various splints were shown and the method of their use demonstrated. It was pointed out that the splints should be such that they could easily be removed for massage and other local treatment. In the acute stage of the disease there was a limit to the patient's tolerance of treatment, and in such cases the skill and judgement of the surgeon might be taxed to the utmost. Once deformity had developed, any forcible movement was sure to be harmful, but gradual stretching by weights or splints could overcome many of these early contractures. In conclusion, Mr. Russell urged the necessity of physicians and surgeons appreciating the value of posture during the acute stage

of the illness, and splintage in the prevention and control of deformity.

Dr. W. S. SYME referred to the difficulty of finding a focus of infection, and urged that the examination of the throat and nose should be more strict than was commonly the case. For example, it was often the most innocent-looking tonsil which showed the greatest degree of infection in the crypts when a thorough examination was made by pressing forwards the pillars and projecting the tonsil towards the observer. With nasal infection even more care was required to demonstrate the freedom from infection of the various sinuses. In some cases where generalized infection had occurred removal of the primary focus did not afford relief, probably because secondary foci were then equally fertile as sources of infection.

Dr. J. N. CRICKSHANK referred to the herpes occasionally observed after protein shock therapy. He described six cases in which severe herpes of the mouth and lips and surrounding area of skin had occurred. Subsequent injection of a fresh vaccine from the same stock was again followed by herpes. One patient had been treated by a vaccine from a different stock without the appearance of herpes. When treated by the vaccine which produced herpes in the other patients he also suffered in the same way. These facts suggested the need for care in selecting a suitable stock vaccine.

Dr. HOWIE mentioned the importance of focal infection in rheumatoid arthritis and allied conditions.

Dr. MANNON GILCHRIST referred to the difficulties in the treatment of rheumatoid arthritis and the problem of individual resistance to such infections. Vigorous application of all measures calculated to raise the patient's general resistance was essential. In the prevention of deformities and limited function movement was important. Pain was a difficult symptom to treat, and in several instances she had found local x-ray treatment of much benefit in its relief. She wished particularly to emphasize the importance of treating the mental attitude of the patient.

Dr. G. H. CLARK had found that a dressing of methyl salicylate and carbolic oil with the application of heat gave in some cases a much better effect than heat alone. He had also obtained better results in some cases with the Greville bath than with ordinary radiant heat.

## HEADACHE.

A discussion on headache took place at the meeting of the Hunterian Society on December 15th, 1924. Mr. H. W. CARSON presided.

Dr. C. O. HAWTHORNE, in opening the subject from the medical side, said that headache was a symptom which demanded a large exercise of care and judgement in the field of differential diagnosis. It existed as a clinical expression of numerous and varied pathological states, and it differed widely in different cases both in its degree and its significance. Nothing could be worse in practice than to regard the complaint of headache as an opportunity of prescribing one or other of the various remedies which had therapeutic value in this direction. To rest content with the temporary benefits which many of these remedies were able to afford might be to relieve the pain, but it would be essentially to neglect the patient. Among conditions of which headache might be an early or the earliest symptom, he mentioned chronic renal disease and also what was commonly spoken of as high blood pressure. He would suggest that the most prompt and efficacious remedial measure to apply in these cases was blood-letting, either by resection or the application of leeches to the temple. Again, everyone would admit that headache might be the sole symptom of tumour of the brain. He urged that every patient with headache should be examined by the ophthalmoscope for changes in the fundus oculi. This examination should be repeated at frequent intervals to secure diagnostic safety. He believed the ophthalmoscope to be a necessary part of the equipment for every clinical examination. There were other intracranial changes which might be manifested by headache, prominent among them the various forms of intracranial syphilis, and again of meningitis. In each of these conditions there were other symptoms, but headache,

might be early and predominating. It was therefore necessary to stress another method of examination—that of lumbar puncture and examination of the cerebro-spinal fluid. In obstinate and severe headache for which no obvious explanation could be obtained it was just as necessary to examine the cerebro-spinal fluid as to examine the fundus oculi. As local causes of headache—occurring, he admitted, rarely, but not to be neglected—he mentioned suppuration in the intranasal sinus, and tabes dorsalis. He then went on to speak of eye-strain as one of the causes of headache. Whether migraine was always due to ocular defects, and was capable of being cured by correction of those defects, he could not say, but no one having a patient suffering from migraine would think of leaving any refractive defect uncorrected. He wondered whether anyone had had the courage to treat an acute attack of migraine by lumbar puncture. It was certain that post-epileptic headache could be relieved by this method, and he would like to see what would happen if the puncture were made at the earliest possible moment in migraine. There still remained headaches for which an explanation had to be found, some of them due to anaemia, some to calcium defect. Another group was associated with gastro-intestinal disturbances. The headache due to bad temper had to be reckoned with, and also the "diplomatic" headache, which was of such great value both in politics and society.

Mr. WILFRED TROTTER spoke on the surgical aspect. There were certain varieties of pain in the head which could by a little inquiry be dismissed from the category of headache. In the headache complained of by the neurotic patient there was a quality which placed it apart; the patient, if questioned, would say that it was not pain but a queer and indescribable sensation. In another class of headache the sensation was like that produced in characteristic trigeminal neuralgia—bouts of pain of agonizing intensity, which the patient invariably compared to puncture with a red-hot needle. A third group was the headache associated with disease of the nasal sinuses. One of the characteristics of the pain under these conditions was its liability to come on at the same time on successive days. Then there was headache associated with definite cranial abnormality, the characteristic of which was severe pain more often in the anterior part of the head than the posterior, particularly behind the eyes, of a throbbing character, and intensified by anything which stimulated the circulation or altered the intracranial tension. Finally there were headaches in connexion with injury to the head. A patient who had received a severe injury to the head was particularly liable to develop severe and disabling headaches, brought on by slight mental anxiety, bright lights, or loud noises. In this headache one must not expect to get any neurological signs whatever. All the signs that Dr. Hawthorne had mentioned would probably be negative. The characteristic feature was the clinical aspect of the case. With regard to the surgical treatment of these cases, it was only necessary to realize that they were due to the bruising of the brain, which was the only organ of the body to have any serious difficulty in recovering from a simple bruise. The one great means of relief was rest in bed, and afterwards, on any sign of relapse or recurrence, the patient should be sent back to bed again. If the headache was persistent and recurrent a simple decompression operation would bring it to an end.

Dr. BERNARD HART dealt with the psychological aspects of headache. He referred to the surprising variability in localization and quality of the headaches in the psychoneuroses. There was no question that a great many conditions which these patients described as headache were not headache in the real sense of the word, but it was necessary to distinguish three types—actual pain headaches, paraesthesia, and the type of headache which denoted not so much pain as great mental disturbance, or, as the patient sometimes expressed it, the feeling that he was standing on his head. A certain number of headaches which occurred in neurasthenic conditions were produced by a mechanism identical with that which produced ordinary headaches, save that the initial link in the chain of causation was a psychological factor. Other headaches, however, might be produced entirely psychogenetically. Of these the first subgroup

would be those produced by suggestion. When patients described themselves as suffering from "helmet" and other classical headaches it might be taken for granted that they had been assiduously studying the literature of the subject. There was also "preoccupation headache," cases in which at one time a general headache occurred which had subsequently become the subject of a psychological preoccupation. Another form was the "projection of incapacity headache," in which the patient, suffering from the typical disability of many neurasthenies, projected his feeling of incapacity into his head, and expressed it as a headache. These distinctions were of practical importance if treatment was to be reasonably founded.

Dr. FIELDEN BRIGGS discussed the dental aspects of the question. He mentioned that the late Sir Lauder Brunton never approached a case of headache without first examining the teeth. Headaches caused by the teeth came under two heads—reflex and toxic. Sir J. DUNDAS-GRANT, while supporting Dr. Hawthorne's view as to the necessity of ophthalmoscopic examination, thought that Dr. Hawthorne had rather underrated the difficulties of the practitioner who was not specially skilled in this form of examination in interpreting properly what he saw. Dr. SYMONDS spoke of headaches due to neuritis of the scalp and—a much rarer cause—disease of the cranium. The former was usually distinguishable from other headaches by the hyperaesthesia of the scalp. Mr. PHILIP FRANKLIN said that most of the headaches which they met with in practice were not really very serious, and those which were serious had usually other symptoms associated with them which gave a clue. The nose specialist had frequently to observe post-operative headaches. Interference with the bone of the nose was a very important factor in causation. Dr. W. H. KELSON advocated the use of the post-nasal mirror in dealing with headaches arising possibly from nasal trouble. Dr. F. HOWARD HUMPHRIS said that high blood pressure and low blood pressure headache were both amenable to electrical treatment. Migraine was amenable to diathermy, and calcium deficiency headache to artificial sunlight.

Dr. HAWTHORNE replied on the matter of the ophthalmoscope. He granted that interpretation was difficult, but observation must necessarily precede interpretation, and the persons who accustomed themselves to regular observation were the persons, after all, who would make themselves expert in interpretation.

### MULTIPLE POLYPOSIS OF THE COLON.

At a meeting of the Surgical Section of the Royal Academy of Medicine in Ireland, held on December 12th, 1924, Mr. R. C. B. MAXSELL in the chair, Sir WILLIAM I. DE COURCY WHEELER read a paper on a case of multiple polyposis of the colon, the specimen and lantern slides of it being shown by Dr. O'FARRELL.

Sir William Wheeler referred to the literature on the subject which connected the condition with chronic ulcerative colitis. The ulcerative process was of such a character that portions of the mucosa and submucosa adjacent to the primary arterial branches were preserved, and these portions remained as ragged tags scattered over the surface of the colon. In a later stage of the disease the orifices of certain of the tubules between the polypi became occluded and retention cysts were formed, which gave rise to the name—colitis polyposa cystica. He thought that the distinction made between adenomata, papillomata, and true polypi in the class of case under review was unnecessary; one condition was probably only a stage in the development of the other. Multiple polypi in the stomach were not very rare, and they were not infrequently found in the caecum and the rectum. A few isolated cases of polypi of the small intestine had been described, and all authorities were agreed that multiple polyposis of the colon was potentially extremely malignant.

The patient in this case was a woman, aged 26, who had been admitted to hospital with a long history of constipation, followed more recently by diarrhoea with the passage of blood and pus. Her temperature ranged from 99° to 101° F. A tumour was detected in the line of the descending colon, and hyperirritability and hypermotility of the colon were observed by the radiologist. When the abdomen was opened in the first instance, the wall of the colon from the caecum to the pelvic colon was found to be rigid, inflamed, and hyperaemic: it gave the impression that if it were bent

unduly it would break. The condition of the colon recalled the condition found in cases of "leather-bottle" stomach: septic inflammation of the mucous membrane was found. A short circuit between the ileum and the rectum was made, and the operation completed by an appendicectomy. Six months later she was again admitted to hospital: she had been free from haemorrhage for four months, but it had then recurred and the tumour could still be felt. The abdomen was again opened and the entire colon removed to the line of the original anastomosis; a tube was passed through the rectum into the small intestine. The patient died on the third day, apparently from peritonitis, but an autopsy was refused. An hour before death there was copious drainage through the tube, with a cessation of vomiting, but this appeared to come just too late for recovery in a case which was a bad surgical risk. The colon weighed  $2\frac{1}{2}$  lb., and was covered with myriads of polypi from the caecum to the pelvic colon. The caecum itself was free from polypi, as was the pelvic colon, which was thought to be an unusual line of demarcation.

Mr. MACAULEY referred to the help obtained in these cases by means of a barium enema. He had recently had a patient, a woman aged about 53, who complained of bleeding from the rectum; he had suspected malignant disease. The bleeding was too severe to make a satisfactory sigmoidoscope examination, and no information was obtained from a rectal examination. A barium enema was given, and the radiologist reported that the signs were characteristic of colitis, evidence of obstruction being absent. At operation the wall of the colon felt indurated, friable, and stiff, as described by Sir W. Wheeler. The abdomen was then closed, and the patient had since reported herself as doing well.

The President and Mr. A. CHANCE joined in the discussion.

#### *Perthes's Disease.*

Mr. H. F. MACAULEY read a paper on Perthes's disease, and showed lantern slides. He demonstrated the radiographic appearances of the upper femoral epiphysis, and showed the persistent progress of this disease, even under prolonged treatment by immobilization and traction. In some cases there was a very definite traumatic history; in others there had been a spontaneous onset, attributable to bacterial or toxic causes. He then discussed briefly the symptoms of the disease in the acute phase, when it was likely to be mistaken for tuberculosis of the hip, and in the latter quiescent stage. The remainder of the paper was mainly concerned with a discussion of the prevalent views on the etiology of the condition, with particular reference to Jansen's theory. Mr. MacAuley believed all the theories were partly true, some applying to some cases and others to the remainder; he did not believe any one theory accounted for all the cases of this malady, which might be due to very different causes. He endeavoured to show how the theories could be corrected, and how trauma, infection, and want of joint balance could all be used to explain the epiphyseal changes. Regarding treatment, he advised immobilization and traction with the limb abducted during the acute phase, and the subsequent use of a walking calliper until the fragments became reunited, which would be about one year later. Though he believed treatment was without effect on the evolution of the epiphyseal changes, he thought it prevented prolongation of the acute stage, and possibly subsequent abduction deformity.

Mr. H. STOKES referred to a case of Perthes's disease, associated with Schlatter's and Köhler's diseases, and he believed that this condition suggested a nutritional cause. Dr. T. J. D. LANE thought it possible that there was some connexion between Perthes's and Köhler's diseases. The condition was, radiologically, very similar, and the prognosis in both diseases was the same—namely, the condition generally healed up with or without treatment. Dr. T. T. O'FARRELL said that it was a matter of great importance in connexion with child hygiene to know what symptoms of Perthes's disease should be looked for first, also to know what could be done by way of prevention. He did not think that the disease could be due to injury. Dr. P. DE BURCA thought that a bacteriological examination of the urine should be made as a routine measure, since it would thus be possible to find out whether the child was suffering from bacterial poisoning or not. He also suggested a complete investigation of the endocrine secretions. Dr. W. STEVENSON believed the deformity of the head of the bone in these cases was caused by the pressure of the muscles, and he thought that, in addition to rest in bed and weight bearing, traction might lessen the fragmentation.

## DISEASES OF ADOLESCENCE.

A MEETING of the Chelsea Clinical Society was held on December 16th, 1924, Dr. GORDON LANE in the chair.

Dr. THEODORE THOMPSON discussed the subject of disease in adolescence, and drew attention to the mental, bodily, and sexual changes which occurred at this period of life. The chief mental abnormalities were epilepsy and hysteria, and he also mentioned dementia praecox. On the physical side he also drew attention to the influence of heredity, climate, and the surrounding temperature. He gave an interesting account of the supposed functions of the ductless glands. With reference to the questions of vice and masturbation, he insisted on the duty of parents and schoolmasters to deal boldly with them. As regards actual disease Dr. Thompson remarked that growing organs were apparently more liable to disease than parts which were not growing. He instanced the effect of rheumatism upon the growing heart, and the incidence of phthisis upon the developing areas of the lungs.

Mr. IVON BACK emphasized the surgical aspect of disease in the adolescent. He believed that much surgical tuberculosis was bovine in origin, and stated that the cows in one European country were all tuberculous. Tuberculous lymphatic glands in the neck were always more numerous than could actually be felt, and he advocated their treatment by artificial sunlight. He thought that it was dangerous to attempt the surgical removal of tuberculous mesenteric glands. He also laid stress upon the hopelessness of trying to remove sarcoma of bones even by amputation.

Dr. CREWSDON THOMAS believed the path of infection of tuberculous cervical glands lay through the tonsils. Dr. ERIC PRITCHARD drew attention to the prevalence of sub-acute appendicitis and enteritis in adolescents, and to the good effect which ultra-violet rays had upon the general health at this period. Dr. ERNEST YOUNG, Mr. GAYMUN JONES, and Mr. A. T. ROGERS spoke favourably of the results of sunlight and of deep x rays in the treatment of certain bone lesions. Dr. GORDON LANE referred to the hereditary tendencies which might be first manifested at the period under discussion. He was a firm believer in the treatment of malignant disease with radium and deep x rays.

## THE PATHOLOGY OF DISEASE OF THE THYROID.

At a meeting of the Liverpool Medical Institution on December 18th, 1924, Dr. G. SCOTT WILLIAMSON discussed the pathological basis of symptoms in thyroid disease.

Dr. Williamson first described the new conception of the anatomy of the thyroid apparatus, and then proceeded to detail the two cycles of function, colloid storage and true secretion. The process of the storage of colloid was discussed in detail, and the typical disorders affecting this function were considered. The most significant fact in this connexion was the existence of two distinct types of endemic goitre, of which the vesicular goitre alone represented a pure disturbance of the "colloid" function. This goitre occurred as a sporadic affection, and it was noted that in the sporadic variety thirty-two out of thirty-eight cases occurred in males at puberty. McCarrison was cited as having succeeded in producing this form of goitre by overfeeding with calcium. This was contrasted with the results of iodine and protein experiments, which resulted in a true hypertrophic enlargement. Attention was called to the necessity of further study being given to the endemic goitres before adopting a wholesale treatment in goitrous zones. A therapeutic suggestion was that calcium medication might be used to supplement iodine treatment in dealing with goitres. Secretory disturbances were shown to have a very clear-cut histopathology. The so-called hyperthyroidisms were disturbances of the secretory function, and were essentially dystrophic states. Thus in this connexion two types of dysthyroidism arose—Graves's disease at one extreme, and myxoedema at the other, or alternating with each other. Graves's disease was shown to arise as a primary condition with a definite histopathology, of which the additional factor was

## POST-ENCEPHALITIC PARALYSIS AGITANS.

A MEETING of the Devon and Exeter Medico-Chirurgical Society was held on December 18th, 1924, the President, Dr. VINCENT SMITH, being in the chair.

Dr. WILLIAM GORDON read notes on two cases of post-encephalitic paralysis agitans. The first patient, a boy aged 15½, had been seen in association with Dr. Foulkes. The initial symptoms had been characterized by fidgeting, with bouts of sleepiness, and the resulting effects were hemiplegia of the left side of a mild degree—as regards loss of power in the limbs—and with very slight paresis of the facial muscles. Nystagmus had been noted occasionally.

At the present time, in addition to the hemiplegic signs, the facies, attitude, and tremors of paralysis agitans had developed, the typical position of the arms when at rest and the "cigarette-rolling" movements of thumb and index finger being also noted during observation in hospital. The second case was that of a man, aged 34, in whom there was mental cloudiness, fixed expression, rigidity, and the general attitude of Parkinson's disease, without tremor. There was also a dry scaly condition of the skin. There were no abnormal reflexes, but there was slight weakness of one external rectus. The patient was unable to walk without support. There was a definite history of encephalitis some four and a half years ago; cerebral symptoms lasted about four weeks, and from that time onwards there had been progressive deterioration to the condition described above.

Dr. Gordon discussed the treatment in these cases, with special reference to Steinach's operation, which did not appear to be applicable to either of the cases. On the other hand, he considered that there was every justification for Letter's treatment, which aimed at bringing about an artificial leucocytosis by means of local irritants applied externally, as, for instance, in the region of the hip. Dr. Gordon had faith also in the use of iodides with arsenic.

Dr. G. L. THORNTON recounted the case of a young man, now aged 29, in whom symptoms of paralysis agitans had shown themselves definitely some three years ago, and who had already reached the paralytic stage of the disease. This patient had served in the navy, and there was a history of a short illness in 1918, in which the cerebral symptoms manifested a diagnosis of encephalitis. Vague neurological manifestations followed, but were considered to be sub-stantiated at the time of his discharge, and for a year subsequent to that date. It had been noted, however, that in spite of his complaint of weakness in the legs, he was able to jump over low obstacles and to run upstairs, which was, of course, easily explained in the light of the now clearly established diagnosis. The interest of the case lay in the contrast between it and those shown by Dr. Gordon, in that, although without doubt a sequela of encephalitis, the Parkinsonian syndrome was uncomplicated, whereby it might be assumed that the original lesion had been confined strictly to the tracts now associated with paralysis agitans.

Dr. F. A. ROREN discussed the question of the apparent interval which elapsed between encephalitis and the onset of paralysis agitans, mentioning the case of a woman who had seemed free from symptoms for one year after an attack of encephalitis lethargica. Dr. G. P. HAWKER warned the meeting not to be deceived by a spurious nystagmus in cases where the ocular muscles might easily show fatigue.

*Tuberculosis following Injury.*  
Mr. R. WAYLAND SMITH showed a youth with a tuberculous lesion of the forehead which had occurred on the site of an abrasion set up by a piece of falling timber. The original wound failed to heal, and tubercle bacilli had been found locally. The family history was healthy and the previous health excellent. The case was one of great medico-legal interest.

Mr. DRYALL mentioned two similar instances: (1) In a butcher who had received an abrasion of a finger when cutting up an ox, and subsequently developed tuberculosis of the finger and forearm. The disease became generalized and proved fatal. (2) In a servant girl in whom tubercle occurred on the site of a scald which, although of the second degree, had remained unhealed for three months, sinuses recurring, as in the case shown by Mr. Wayland Smith.

A-colloidism. Secondary Graves's disease usually presented an intoxication symptom first, which was followed by an exophthalmic train of symptoms. Though the gland in secondary Graves's disease contained colloid, the colloid was ineffective in that it was encysted. Toxic goitre, so called, was a simple dysthyroidism and had the same basic pathology as secondary Graves's disease, except that the colloid was still circulating while secretory activity in some areas was producing stored secretion which was brought out in the history, and if Plummer's therapeutic iodine test was applied; primary Graves's disease was peculiar in manifesting a need for iodine, whereas simple dysthyroidism (toxic goitre) and secondary Graves's disease were made worse by this administration. This distinction was demanded by the histopathology of the condition. Myxoedema was shown to have a very definite histopathology. It was clearly not a simple atrophy, but a disease *sui generis*, and essentially a dysthyroidism of a distinct order. Perhaps the insufficiency of thyroid medication in myxoedema might be explained in this way. Dr. Scott Williamson emphasized the need of remembering that each individual was a law unto himself as to the amount of thyroid activity needed by his physiological, and pregnancy were not to be looked on as pathological, since they all exhibited only a simple hypertrophy. Disease also gave rise to hypertrophy, and of the greatest importance was the hypertrophy associated with status lymphaticus. This association accounted for nearly all the sudden deaths in goitre. Since secondary Graves's disease or simple dysthyroidism arose as a sequel of hypertrophy, it became necessary for the surgeon to exclude carefully status lymphaticus in all cases of goitre, no matter what were the train of symptoms; this was emphatically necessary up to the age of 25 years in men and women. Primary Graves's disease was shown to have a peculiar thymus condition, differing from that of status lymphaticus. Dr. A. C. WILSON was not satisfied that surgery was the only remedy for exophthalmic goitre. For twelve years he had used *B. coli* vaccines in shock doses with good results; he had treated eighteen cases of exophthalmic goitre, including two or three desperate cases, with success. In his experience the vaccine had not the same value in simple goitre. Two recent cases were of interest: a lady with exophthalmic goitre who had tried several other treatments, including x rays, was cured by six injections, and in twelve months gained two stone in weight. A spaniel dog with a simple goitre the size of a lemon was cured by two injections, all signs clearing up in eight weeks. The dose of *B. coli* used was 500 million.

Dr. N. B. CARON described three cases of congenital goitre in newly born infants. Severe dyspnoea was a prominent symptom in two of the cases.

Professor BLAIR BELL said that his own interest in the thyroid had been both philosophical and practical. His experimental work had shown that the thyroid, in association with the rest of the hormonopoietic system, was directly related, not only with the individual metabolism, but also with the reproductive. He laid stress on the necessity of considerable knowledge of comparative anatomy and physiology in interpreting the nature, variations, and disorders of organs of internal secretion. He referred to the fact that removal of the thyroid-parathyroid apparatus in the cat caused death within forty-eight hours, unless the animal was pregnant and the thyroid of the foetus was so far developed that secretion was generated and passed into the circulation of the mother, in which circumstances she remained well until after parturition, when she died. This was comparable with the improvement seen in hypothyroidic patients during pregnancy. Reference was also made to the evolutionary aspect of the disease as demonstrated by the normal condition of exophthalmos in association with epithelial hyperplasia, as seen in Graves's disease, which he had described in the lemur, and the phenomena of aeromegaly which were seen normally in the higher apes, as suggested by Keith. Professor Blair Bell believed that the hypertrophy of the thyroid to which Dr. Williamson referred was not quantitative but qualitative. In the rabbit, ordinarily there was but little colloid secretion, but during pregnancy there was often an enormous quantity.

## Reviews.

### THE HUMAN TESTIS.

SIR ARCHIBALD GARROD, in his recent Harveian Oration, said: "It is natural, nay inevitable, that as medical science grows and advances, some of the workers in the field should elect to follow the path which leads through the laboratory, whereas to others the wards make a stronger appeal; and thus is taking place a differentiation of medical workers into distinct groups, and there is danger that the fission may go too far."

It is therefore with special pleasure that I review at length a monograph by Dr. Max Thorek of Chicago on *The Human Testis and its Diseases*,<sup>1</sup> for, not satisfied with a wide surgical experience, he has also devoted time and attention to experimental and laboratory investigations, and, in my judgement, it is this conscientious and painstaking endeavour to familiarize himself practically with the whole subject which has enabled him to sift and correlate the facts relating not only to his own work, but to that contained in the numerous publications of other investigators. The conclusions he reaches strike the reader as being based upon sound judgement founded on first-hand clinical, experimental, and laboratory knowledge and experience of the subject. He is confident that continued research will soon establish definitely the identity of the internal secretion of the testis and its chemical composition, and supports this opinion by reference to the works of Winniwater, who claims to have followed the transition of mitochondria to crystalloids; he refers also to the work of Duesburg, Iscovesco, and Mulon on the same lines. He does not accept the view that the Leydig cells are controlled by centres situated in the hypothalamic region or elsewhere, because they continue to live after transplantation of the testis.

The history of our knowledge of the functions of the Leydig, seminiferous, and Sertoli cells, from the earliest times until now, is discussed. The view that the testis has a double function is an old one. The point, however, which has caused particular dispute is not the question of a separate testicular secretion which influences sex characters, but rather, what particular testicular structure is responsible for such secretion, and how it acts. There seems now to be general consensus of opinion that the interstitial cells are entirely responsible for sex potency, libido, eroticism, and retention of the secondary sexual characters. This is borne out by the results of castration and experimental transplantation in men and animals.

Dr. Thorek devotes about one hundred pages to the pathology of the testicle. He gives a short analysis of twenty-four cases, diagnosed as strangulated hernia, in which torsion of the spermatic cord was found. Ten of these cases were observed by himself. He makes another analysis of seventy-nine cases of radical operation for testicular growth, and concludes that the evidence is sufficient to show that a radical operation gives better results than simple castration.

Next an admirable account is given of the effects of the internal secretion of the testes upon growth and metabolism. Weil's studies relating to body proportions and sex-gland abnormalities are summarized, and Pézard's researches on the effects of castration are fully related. A fresh account is given of the strange Russian religious sect, the Skopzies, founded on a recent study by William Koch, who resided among them during the war. Their religion requires male members of the sect to submit to castration at some period in early life. Koch recognized four types: (1) the ordinary, with long extremities; (2) gigantism; (3) a type with acromegaly; and (4) a type with hypophyseal adiposity. The type seemed to depend upon the age at which the castration was performed.

After recording a number of interesting facts concerning the physical and psychic characters of castrates, Thorek concludes that the incretory function of the testes is of vital

importance for the well-being of the individual, and that its correlation with other endocrine glands is fundamental. There are three types of eunuchoidism—(1) feminism; (2) genito-dystrophic gerodermia, a condition where the male is "old and seems young," or is "young and seems old"; (3) Kall's, or the tardy type, which appears after normal general sexual development when regressive symptoms develop. Precocious puberty, dwarfism, and gigantism, and their relation to gonadal and other endocrine dysfunctions, are fully considered, and the descriptions are illustrated by cases and some excellent photographs.

A good account is given of Steinach's vas-o-ligation experiments and of the so-called "rejuvenation" operation. Thorek's own experiments on the higher apes and operations on a number of human beings according to Steinach's method gave results which in some instances were good, in others disappointing. The author provides the following summary of his opinions:

"(1) I am opposed to the term 'rejuvenation.' It is misleading and may create a great deal of harm, particularly with the laity, who are bound to exaggerate.

"(2) More clinical data from unbiased sources are necessary to form a definite opinion. Human data are the only reliable criteria, because what may hold true in the lower form of mammalia may often be found reversed in the human.

"(3) Clinical evidence supported by laboratory checking will in due time establish the merits or demerits of the Steinach procedure. Presently a mass of evidence is inclined to pessimism, although some good results are reported from some quarters."

In a chapter on "The Male Climacteric" the author states that between 55 and 65 there is in many males a marked mental and bodily change, associated in some instances with arterio-sclerosis; in others a type of neurasthenia and involuntal melancholia well known to neurologists and psychiatrists may occur. Steinach's experiments suggesting that the substances of internal secretion have a selective storage action in the central nervous system are of especial interest in relation to these conditions.

Thorek transplanted testes in six rhesus monkeys and obtained some interesting results. He found that when x rays were applied the transplant thrived, whereas in the control animal in which the transplant was not x-rayed it was absorbed. This he explains on the ground that around the x-rayed transplant few leucocytes were to be seen, whereas around the control they were abundant. He gives the dose of x rays which preserves the interstitial cells and ensures an adequate blood supply to enable them to thrive and function.

A very complete survey is given of reported cases of transplantation by various workers, including Voronoff. There is a strong biological reason why grafts from bovines, dogs, etc., are not successful when applied to man, and the investigations by Nuttall of blood affinity of man with the Simiidae offers some assurance of successful transplantation of "monkey gland." The work was in the press before the publication of Carr's investigations upon "The behaviour of the testis in transplantation, experimental cryptorchidism, vasectomy, scrotal insulation, and heat application" was published in *Endocrinology* (July, 1924). This important work, independently confirmed by a Japanese investigator, Fukui, appears to prove that "the scrotum of mammals is a local thermo-regulator for the testis, and that the regulatory or functional capacities are indispensable for the production of differentiated germ cells or the maintenance of those already produced." A very striking experiment of Fukui was this: Both testes of an animal were elevated into the peritoneal cavity, but artificially cooled on one side in the region of the testis. He found in the course of a few days that the testis which had been kept cooled was normal, whereas the uncooled testis was degenerated.

A chapter of particular interest to psychiatrists is that on dementia precox and the gonads. An account is first given of the investigations of Gibbs (*Archives of Neurology and Psychiatry*, 1923, ix, 73), which showed that the failure in sex growth and behaviour was due to a biological inadequacy, but it is probable that the failure is not limited to the sex mechanism. "There is a total functional deficiency in most of these patients. Adequate functional activity of the thyroid, pituitary, and suprarenals seems to be necessary

<sup>1</sup> *The Human Testis and its Diseases*. By Max Thorek, M.D. London: J. B. Lippincott Company. 1924. (Med. Bro. pp. x + 547; 303 figures. 3s. net.)

for sex growth." This is entirely in accordance with my histological observations of pituitary, thyroid, and adrenal glands in one hundred hospital and asylum cases.

Undue prominence is unfortunately given to the work of Matsumoto, who merely overlooked my specimens and was in no way responsible for the findings, as he only confirmed what I had already explicitly stated in a paper published in this JOURNAL (1919, vol. ii, pp. 655, 698, 737) on the examination of the testes in one hundred hospital and asylum cases. Thorek refers later to this paper in appreciative terms, as well as to another paper on "The interstitial cells in dementia praecox and primary post-adolescent dementia" by myself and Prados-y-Such. The conclusions are quoted verbatim, together with the tabular summary of results and most of the original illustrations.

It is interesting to note that at the present time Thorek has a number of cases of dementia praecox under observation in which human testicles have been implanted. Reports of some seem hopeful, but it must be remembered that spontaneous remission of symptoms is not unknown. I am doubtful, having regard to the fact that this disease is in all probability a genetic inadequacy affecting many organs of the body, and especially the telencephalon, whether any treatment is likely to give more than temporary benefit. However, seeing that modern investigations show that the interstitial cells have an energizing effect upon all the organs of the body, and that, as Thorek shows, an implanted testicle may retain its interstitial cells, such operative procedure is of great interest and importance, and is more likely than injections to be attended by good results. Still, having regard to the remarkable effects of insulin, it is possible that an analogous substance may be prepared from the testes; Steinach's experiments, however, suggest that it is only likely to have an effect on the central nervous system if the substance be obtained from animals of the same species—either anthropoid apes or man.

As a result of his own experiments and observations Thorek concludes "that the practicability of therapeutic transplantation from the higher apes to man is proved beyond any doubt." The indications and contraindications for sex gland transplantations in the male are fully discussed; moreover, all the details of the operation are very carefully and clearly described, and the reader is helped to follow the technique by numerous diagrams and photographs. The concluding chapters deal with such subjects as neuroses of the testicle, diseases of the scrotum, varicocele, hydrocele, and their medical and surgical treatment.

Thorek's authoritative standard work should prove of great value to the medical profession on account of its clear exposition, practical character, first-hand knowledge, and up-to-dateness. The book is illustrated by 308 excellent diagrams, photographs, and photomicrographs. There is a good bibliography at the end of each chapter, and an index of over 500 authors cited.

FREDERICK W. MOTT.

#### "E.R.A." TREATMENT.

"The Abrams Treatment" in Practice: An Investigation, by Dr. G. LAUGHTON SCOTT, is a small volume which we have read with much interest. The writer has attempted no general examination of the doctrines of the "E.R.A." cult, but has confined his attention to two questions only: (1) whether the instrument of treatment, the oscilloclast, produces clinical results which cannot be denied; and (2) whether the instrument gives rise to demonstrable electrical phenomena which might explain any positive results."

The first problem is treated in the body of the book, and part of the second question is dealt with in an appendix in which Messrs. A. S. E. Ackermann and W. Clark, consulting engineers, report upon the machine. Messrs. Ackermann and Clark conclude as follows:

"Having made the experiments and investigations herein recorded, we are satisfied that a patient, when treated as were our subjects by the oscilloclasts we used, is subjected to the electrical pressure of the supply mains, whether the current in

the mains is alternating or direct, and that this pressure is interrupted about 200 times per minute. We are also satisfied that these electrical effects could be produced by a more simple and less costly apparatus."

They mention in their report that earlier investigations of another model of the oscilloclast failed to show that it produced any electrical effects in its terminal leads, but, as the reporters say, "it is clear the oscilloclasts with which we experimented were not of the same design as that illustrated and described at page 177 of the *Lancet* of January 26th, 1924." The criticisms of the earlier types of oscilloclasts examined by previous workers were so drastic that it is not surprising that the pattern of apparatus has been changed so as to avoid the obvious criticism that it does not do anything at all.

Information concerning the structure of the oscilloclast has been scanty; these machines are leased (not sold) for about £150, and one of the conditions of the lease is, we are informed, that the instrument shall not be opened. Messrs. Ackermann and Clark show that the greater portion of the apparatus in the oscilloclast is functionless, and that the essential part of the machine is a simple rocking magnetic interrupter.

The electrical effect of the machine examined is that, with each interruption, a very small current of the order of a micro-ampère flows to the patient (the actual quantity depending on his insulation from earth), and this current gives him an electrostatic charge of the same voltage as that of the supply mains. The current flowing into and charging patients can be demonstrated by means of a gold leaf electroscope or by a telephone receiver. If the patient's skin be stroked with a conducting substance (for example, a finger) leading to a body—as, for instance, the observer—possessing electrostatic capacity, a rough feeling is experienced; this effect is presumably due to a small current passing through the skin from the patient to the other body and stimulating the erector pilae muscles. There is, of course, nothing very surprising or unusual about a machine which produces such effects. The really remarkable thing about earlier patterns of oscilloclasts was that a machine should have been so constructed that when a current from the supply mains was put in at one end no electricity whatever escaped at the other.

The reports of the clinical effects produced by the instrument are much more remarkable than the electrical effects, for Dr. Laughton Scott relates cases of his own and of three other medical men, and claims that treatment with the oscilloclast produced marked benefit in cases of tuberculous, chronic local infections, exophthalmic goitre, and various other conditions. In particular, the observers found that treatment had a marked effect in reducing temperature in cases of chronic pyrexia. The author concludes:

"After a year's work, the writer is unable to avoid the conclusion that the instrument exercises in favourable cases an exceedingly powerful influence on general health, which in the treatment of particular diseases may be, and frequently has been, very useful."

Dr. Laughton Scott is careful to emphasize the fact that he in no way accepts the general doctrines of the "E.R.A." cult; his position is summed up in the following words:

"If the electrical phenomena described should thus be found to account for all the effects of the oscilloclast, the main fabric of Abrams's work would fall to the ground. But in its place the study of the therapeutic value of periodic low electrical pressure would arise, the possibilities of which might be considerable."

This position appears to be unexceptionable. There are few therapeutic agents which have excited such high hopes and yielded such severe disappointments as has electricity. Electro-therapeutics, moreover, has had the misfortune to be exploited repeatedly by unscrupulous quacks. These facts, however, are no reason for not examining as exhaustively as possible any method that offers any promise. Paracelsus claimed that he had sought truth everywhere, even when it was hidden in the stews, and Dr. Laughton Scott is to be congratulated if he has isolated a kernel of truth from the doctrines of the "E.R.A." cult.

The followers of the "E.R.A." cult have been attacked repeatedly in the medical journals of this and other countries, the essence of the charges against them being that they

"The Abrams Treatment" in Practice: An Investigation. By G. LAUGHTON SCOTT, M.R.C.S., L.R.C.P., B.A. Oxon. London: Geoffrey Blaisdell. (Cr. 8vo, pp. 155; one diagram. 5s.)

have claimed to possess a universal cure-all and have declined to put forward any intelligible explanation of their method. The same rules hold for medicine as for other sciences. Any new theory, however improbable, deserves impartial investigation, provided that reasonable evidence is put forward in its support, and provided that no attempt is made to preserve secrecy but the fullest information and facilities are given to all investigators who desire to check the observations described. The leaders of the "E.R.A." cult violated these rules by patenting their apparatus and leasing it at a very high price, and at the same time doing their utmost to preserve secrecy regarding its method of construction.

We express no opinion regarding the clinical results that Dr. Laughton Scott records, but we must note that although he has shown that the modern type of oscilloclast produces electrical effects, yet these effects scarcely seem adequate to explain the clinical results he has described. It would be very extraordinary if such feeble currents of low intensity should produce any demonstrable clinical effects. Dr. Laughton Scott has, however, described his methods fully, and anyone who is interested can test them for himself, and it would be perfectly easy to make certain obvious controls. Dr. Laughton Scott informs us that, in order to avoid any suggestion that he is exploiting a patent or secret remedy, he has arranged for the Medical Supply Association to make, and to supply at an ordinary trade profit, an apparatus which will produce the electrical changes, with which he claims to have produced his successful clinical results.

#### MODERN CLINICAL METHODS.

DRS. BEAUMONT and DODDS are greatly to be congratulated on having succeeded in bringing into the compass of a small book a reliable account of some of the more important new methods of clinical and laboratory investigation of disease. It is difficult for practitioners to keep abreast of the innovations that are being made in clinical methods and in modern treatment. *Recent Advances in Medicine* offers in concise form not only the technique of the new methods, but a tentative valuation of them: What every practitioner asks when he hears that some investigation that is strange to him has been proposed or performed on his patient is, What is the practical importance of the results obtained?

As examples we may quote from the tests of renal function that in obstetric cases "premature labour should be induced if (a) the blood urea and non-protein nitrogen contents are above 40 mg. per 100 c.cm., (b) the hepatic tests become positive." On the other hand, "from the medical aspect renal function tests fall short in the fact that they do not provide a diagnosis and give a poor idea with regard to prognosis."

This way of stating the case is admirable. We want to know how to advise our patients. Many investigations are in the nature of trials of claims made for the tests rather than of means to afford useful information for individual patients. It is imperative that such trials shall be carried out, but often the practitioner is at a loss to know to which category a proposed test belongs. This book will enable him to decide. It is not to be supposed that the judgements of the authors are final, but for the present time it serves its purpose excellently. To turn to another use of this work, nowadays many practitioners are both willing and competent to carry out laboratory tests not requiring elaborate apparatus. The technique of the tests is described in sufficient detail to make the volume a laboratory handbook; or at least it will enable the reader to decide whether the method is beyond the resources of himself and his private laboratory.

The authors have not confined their study to methods of examination alone. They have included some most valuable chapters on treatment; we refer in particular to the treatment of diabetes, of gastric and duodenal ulcers, of asthma

and urticaria, and the use of some cardio-therapeutic measures.

The book is well illustrated and well printed. It is likely to be successful because it meets adequately a real demand.

#### BIOCHEMISTRY AND HUMAN PHYSIOLOGY.

WE have great pleasure in welcoming the appearance of a second edition of Mr. PARSONS's book *Fundamentals of Biochemistry in Relation to Human Physiology*.<sup>1</sup> It is particularly difficult to write about biochemistry without becoming involved in a maze of structural formulae and other essential but dry details, and elementary textbooks are specially liable to degenerate into a recital of somewhat disconnected facts. Mr. Parsons, however, has succeeded in producing a clear and readable introduction to his subject, and the fact that a second edition has appeared only eighteen months after the first shows that these qualities have been appreciated.

Only minor alterations have been made in preparing the new edition, but the book has been brought thoroughly up to date, and various errors and misprints in the first edition have been corrected. An account of the most recent views as to the part played by lactic acid in muscle contraction has been introduced into the chapter on the utilization of carbohydrates, and an account of the functions of insulin has been added to the chapter on diabetes. New theories are also given concerning the mode of origin of creatinine, the chemical constitution of glucose, and the structural formula of urea.

The essential feature of the book is that it gives a really readable account of those fundamental facts of biochemistry which are of special importance in medicine, and the work is therefore admirably adapted for medical students, and also for medical practitioners who desire to refresh their knowledge of this subject.

#### COLOUR VISION.

IN noticing the first edition of Sir JOHN PARSONS's *Introduction to the Study of Colour Vision*, we expressed the opinion that it was a valuable book. This judgement has been confirmed by the call for a second edition.<sup>2</sup> The author has taken note of the important work which has been done since 1915; thus he gives a satisfactory summary of Ives's researches into the phenomena of recurrent vision. It would, perhaps, have been as well in this, and some other cases of postulated mathematical "laws," to reproduce the numerical data as well as small-scale diagrams. The non-mathematical reader is sometimes overawed by formulae, the arithmetical justification of which is scanty. It is, however, difficult to give a full account of so large a subject in one volume, and both Sir John Parsons and his readers are to be congratulated on the appearance of the new edition.

#### DIVISION OF THE RENAL NERVES.

THE *Archives Urologiques de la Clinique de Necker*<sup>3</sup> contains Dr. Flandrin's paper on the nerve supply of the kidney. The author makes a practice in certain cases of exposing the nerves on the pedicle of the kidney and deliberately dividing them, and his article contains a description of the technique of his operation and the best manner of recognizing the delicate nerve fibrils. The most important portion of the paper, however, is probably the section dealing with the action of the nervous system on renal secretion.

In summing up, Dr. Flandrin states that he has found that division of the nerves of the pedicle is particularly useful as a method of relieving pain in cases of pyelitis and

movable kidney. In his experience this practice has not been followed by any untoward results with regard to excretion, although laboratory experiments have shown that the innervation of the kidney modifies the excretion of water and chlorides.

### EGYPTIAN MUMMIES.

THE history of mummification is not only of profound importance to the Egyptologist and archaeologist; it has much interest for the anatomist, by reason of its influence upon the early development of his science, and also for the student of the history of medicine. Professor ELLIOT SMITH and Mr. WARREN R. DAWSON have presented us, in a volume entitled *Egyptian Mummies*,<sup>2</sup> with a most fascinating sketch of the development of the process of mummification, and have suggested its far-reaching effects and importance. More than two centuries ago the theory was advanced that the first crado attempts to prevent corruption of the dead body had been suggested by the arrest of decomposition found on examination of many of the corpses buried in the shallow graves in the hot dry Egyptian sand. A number of other and more fanciful explanations have been advanced to account for the origin of this interesting custom, but so far we are compelled to speculate as to the motives which induced the procedure in the first instance. Whatever the origin, it seems clear that for three thousand years the art was practised with increasing skill, two objects being constantly before the embalmers—to prevent decomposition and to preserve the actual form and identity of the individual.

At first the attempts at preservation were very simple and quite inadequate, some material, possibly natron, being applied to the surface of the body, which was then wrapped in a series of bandages. Later the viscera, with the exception of the heart, were removed through a wound (generally found on the left side) and placed in Canopic jars. The Canopic jars were used from ancient times, and were frequently decorated and inscribed. Their number was constant, four invariably being used. In the first was placed the liver, in the second the stomach, in the third the lungs, and the intestines were deposited in the fourth. The heart was never removed; the treatment of the kidneys was not so constant, but usually they were left in position. After excision of the organs the body was embalmed, and the body cavity packed with sawdust and balls of linen impregnated with resin. The essential preservative agent for embalming the body was common salt, but analyses of the resins have proved that balsams and the woods of various aromatic trees, especially juniper, were also used. Even in the earlier remains there is evidence suggesting that an attempt was made to produce a model of the individual as well as to preserve the tissues. With the acquisition of greater skill, the brain was removed piecemeal

through the cribiform plate of the ethmoid, and the cavity of the cranium packed with strips of linen soaked in resin. A further development was the evolution of an elaborate method of packing the trunk and limbs to avoid the great distortion consequent upon shrinkage of the tissues. During the later history of the subject, in an obvious effort to make the whole as complete as possible and convert it into a "portrait statue," mummification became a very lengthy process, calling for high skill. Not only were the limbs and trunk padded and the organs restored, after embalming, to the body cavity, but the swathed mummy was painted in as realistic a manner as possible. It is of interest to find that with the greater elaboration of this external decoration, the processes required for preservation of the body became less adequate, and by degrees less attention was given to the body and more and more to the wrappings.

In order to unravel this history a vast number of mummies have been examined, and their study has brought to light valuable and interesting information regarding diseases to be found in those distant times. Although the pathological processes which may be recognized in the mummified body are very limited, quite a number of conditions have been identified. Most of the diseases are of necessity those affecting bone, but several cases of arterial disease have been found, and even the presence of vesical calculi and pleural and appendicular adhesions noted. The absence of any true example of rickets or syphilitic disease, and the non-appearance of true cancer until the more recent dynasties, although several cases of sarcoma have been discovered, is significant and of considerable interest. One case of gout, one of leprosy, and evidence of tuberculous disease have been encountered. Mastoid trouble was of frequent occurrence. Examination of the joints has shown that very few pre-dynastic Nubians ever reached adult life without exhibiting the changes of rheumatoid arthritis, a disease common at all periods. Dental caries was rare until the advent of luxury, but alveolar abscess

from infection of the pulp cavity exposed by wearing down of the teeth is not infrequently revealed.

Information about the treatment of disease is scanty, and so far no bodies examined have afforded any evidence of surgical procedures other than the use of splints. The discovery of the remains of mice in the alimentary tract of several children suggests that this animal was used, as it still is in some countries, as a children's medicine.

### NOTES ON BOOKS.

*How is your Heart?*<sup>3</sup> and *Your Heart and how to take Care of it*<sup>4</sup> are two books by American authors which have been written specially for the education of the lay public. The former, by Dr. S. CALVIN SMITH of Philadelphia, is written in a style which is likely to appeal to readers who have no

<sup>2</sup> *How is your Heart?* By S. Calvin Smith, M.S., M.D. With an introduction by Sir Thomas Horder, Bt., M.D., F.R.C.P. London and New York: Cassell and Co., Ltd. 1924. (Cr. 8vo, pp. 204, 5s. net.)  
<sup>3</sup> *Your Heart and how to take Care of it.* By Robert H. Babcock, M.D., LL.D. New York: D. Appleton and Co. 1924. (Cr. 8vo, pp. 235; 6 illustrations. 5s. net.)

<sup>1</sup> *Egyptian Mummies.* By G. Elliot Smith and Warren R. Dawson. London: G. Allen and Unwin, Ltd. 1924. (Post 4to, pp. 190; 48 woodcuts, 25 other illustrations. 25s. net.)

Queen Nozme, the wife of Hrihor, the first king of the XXIIst Dynasty (Thebes). The mummy belongs to the transition period when the embalmers were attempting to restore the form. (Woodcut by A. Horace Gerrard.)

previous knowledge of the heart and its functions. The author's object is to direct attention to the various causes and earliest symptoms of heart disease, so that affections of the heart may be recognized and treated at the earliest possible moment in order to avoid much preventable cardiac disability in later life. The subject is treated in considerable detail, and many of the minor factors which militate against an efficient circulation are explained in a rational way. It is usually difficult to explain a technical subject to an untrained person, but we feel that Dr. Smith has succeeded in producing a book which should serve its avowed object. There may be a difference of opinion about doctors addressing the public on medical subjects, but we notice that Dr. Calvin Smith does not anywhere mention his address, and the copy we have received has been printed in this country. We think it right to our readers to mention that the author should not be confused with another member of the profession of the same name who is on the British Medical Register. The second book, by Dr. ROBERT H. BABCOCK, while also addressed to the public, is much more technical. The anatomy and physiology are described in too much detail, and terms are employed which will tend rather to confuse than help the popular reader. Otherwise the information contained is mostly sound and follows in general the same lines as the other volume.

A revised edition of the useful little pamphlet *To Wives and Mothers: How to Keep Yourselves and your Children Well and Strong*<sup>9</sup> has recently been issued. Its popularity is evidenced by the fact that its issue has reached 285,000. The pamphlet is compiled by the Association of Infant Welfare and Maternity Centres. As the committee responsible for it consists of certain leading authorities on child welfare, together with some medical officers of welfare centres and lay members practically interested in mothercraft, its contents may be taken as representing the most modern and practical teaching on this subject, standardized as far as is possible. It is not intended to replace expert medical advice, but rather does it represent excellent "notes" which an intelligent mother might take from the health talks of a doctor. Information is given clearly and concisely under good headings, and there is an index. In the chapter on care of the infant the statement is made that "until the cord is healed the baby should not be immersed in the bath water"; this teaching is contrary to the practice usually adopted by midwives. The method of breast-feeding is described fully, together with notes on mixed feeding and weaning. The management of children from 1 to 5 years is referred to, with a few words on character training. Other sections deal briefly with the usual infantile ailments, the common infectious diseases, and emergencies. The importance of sunshine, fresh air, and cleanliness is indicated. A few simple recipes, hints on washing, and directions for making a knitted outfit for the baby complete a most instructive little guide.

*Lessons on the Care of Infants*,<sup>11</sup> by Mrs. WATSON, is a revised edition of a small pamphlet first published in 1907. There is a preface and introduction by Mr. BENJAMIN BROADBENT, ex-Mayor of Huddersfield, whose interest in the welfare of mothers and children is well known. There are five lessons—on natural food, artificial food, clothes, sleep and fresh air, and general care. Simple information is given on these subjects and at the end of each lesson are a few questions. It should prove a useful little pamphlet to school teachers and those who give instruction in mothercraft.

The *Manuel de petite chirurgie* of MM. ARDIN-DELTEIL and P. SOUBEYRAN has now reached its third edition.<sup>12</sup> It is a large book of 917 pages, well illustrated, containing an account of the essentials of minor surgery, and ending with the technique of necropsy. The book follows traditional lines and gives a fair account of antiseptics, anaesthesia, splints, etc., and various of the lesser operations. It is intended for practitioners, students, and nurses, and will not lead them astray, but a book of this size might have been expected to reflect more clearly advances in surgical pathology and treatment.

Sir ARCHIBALD GARROD's Harveian Oration on *The Debt of Science to Medicine*,<sup>13</sup> published in our columns on October 25th, 1924 (p. 747), has been printed in a pamphlet published by the Oxford University Press.

<sup>9</sup> National League for Health, Maternity, and Child Welfare, 117, Piccadilly, W. 1924. (Demy 8vo, pp. 53. 5s. post free.)

<sup>11</sup> *Lessons on the Care of Infants (for use in schools)*. By Mrs. Watson. With a preface and introduction by Benjamin Broadbent, C.B.E., LL.D., M.A., J.P. London: Longmans, Green and Co. 1923. (Cr. 8vo, pp. 19; frontispiece. 6d. net.)

<sup>12</sup> *Manuel de petite chirurgie et de technique médicale journalière*. Par P. Ardin-Delteil et P. Soubeyrans. Troisième édition. Paris: Masson et Cie. 1923. (Roy. 8vo, pp. 927; 501 figures. Fr. 45.)

<sup>13</sup> *The Debt of Science to Medicine*. Oxford: By the Clarendon Press. 1924. (Med. 8vo, pp. 30. 2s. 6d.)

Dr. LOUISE BRINK's monograph on *Women Characters in Richard Wagner*<sup>14</sup> is a study of *The Ring* from the standpoint of psycho-analysis. The work is divided into two parts, dealing respectively with the psychic problem and the problem in the drama, and traces a close relation between Wagner's drama and his psychic life. A bibliography of psycho-analytic works bearing on literature and mythology is appended.

The "Wellcome" Photographic Exposure Calculator<sup>15</sup> for 1925 contains the usual memoranda, with certain additions. Two methods of developing with the aid of a tabloid densitometer are described, and a comprehensive list of the comparative speeds of development of papers and lantern slides is given. Over 280 kinds of plates and films, including the later varieties, and more than 100 kinds of bromide and gas-light papers are classified.

<sup>14</sup> *Women Characters in Richard Wagner*. By Louise Brink, Ph.D. Nervous and Mental Disease Monograph Series, No. 37. New York and Washington: Nervous and Mental Diseases Publishing Company. 1924. (Med. 8vo, pp. xv + 125.)

<sup>15</sup> London: Burroughs Wellcome and Co. 1925. Price 1s. 6d.

## MOTOR NOTES FOR MEDICAL MEN.

### CHANGING CONDITIONS IN 1925.

By H. MASSAC BUIST.

THE three outstanding fresh phases of motor enterprise in the New Year which have a direct bearing on the medical man's use of a car are:

(a) The readjustment of the broken period licence charges, which comes into operation on New Year's Day.

(b) The Road Traffic Bill, which will be introduced in February by Lieut.-Colonel Wilfred Ashley, Minister of Transport, to consolidate the law in regard to the use of vehicles on the road; it will, it is anticipated, abolish the twenty miles an hour and all other speed limits, require the evidence of at least two witnesses before a motorist can be convicted of dangerous driving, and make the use of rear lights compulsory for all vehicles on the road, including pedal bicycles.

(c) The introduction of a remodelled scheme for the safeguarding of industries, whereby the hard-pressed British motor car maker will be shielded in some degree against the competition of car industries in other countries, all of which are assured of their home markets.

Medical men who are relatively new to motoring may be reminded that all vehicle licences have to be taken out at the New Year; that it is not usual to give more than six days' grace in face of the opportunity offered to send in the necessary papers, and so forth, a fortnight before the end of the year.

### SITUATION IN REGARD TO LICENCES.

The new arrangement in regard to taking out what are called broken period licences for cars does not concern the owner who takes out a licence during the first month of the year. It is in the nature of an adjustment, as distinct from a concession. In short, the revenue does not stand to lose anything by it. Like all changes, of course, examples can be cited in which it causes hardship on the motor owner by comparison with the situation that obtained formerly. These matters, however, have to be arranged always on the principle of securing the greatest good to the greatest number. From that point of view the readjustment is more equitable in the majority of cases. It is possible to obtain a quarterly licence now on payment of 27½ per cent. of a full annual licence. If a broken quarter is taken into account, together with what remains of the calendar year, there is a calculation of "one-twelfth of the full annual rate of duty for each month, or part of a month, included in the given period, and a further amount calculated at the rate of 5 per cent. of the amount so ascertained." The car owner has to pay one-third of the quarterly rate for one month, two-thirds for two months, and the full rate for any balance of weeks or days over two months.

### CAR TAXATION.

As far as motor taxation is concerned, it is extremely unlikely that any reduction in car licences will be made in

the Budget this year. The reason is that, even as the present scale of licences exceeds anything that was anticipated when it was introduced, so, unfortunately, does the expenditure on roads. It is being realized that this is becoming more effective, and that motorists will obtain full value for their money.

Again, it is now abundantly plain that the one branch of the world's industry which in general might be said to suffer from the licence scheme—it has an overwhelming advantage in every other respect—is American manufacturing and export. It is already clear that practically all the leading makers in the United States will shortly produce engines which will come out much more favourably under European engine rating schemes than the power plant they have put in their vehicles hitherto. Consequently any hardship under that head will tend to diminish. Current types of transatlantic cars enjoy such an enormous advantage in the matters of low initial cost, and so forth, that any item of extra tax would have to be paid for more than a dozen years before an owner's costs would begin to be on a par—under the combined heads of initial purchase price and licence fees—with a home-made car.

#### SAFER NIGHT DRIVING.

Probably medical men are the section of the car-using community which stands most to benefit by the legislation to be introduced in February concerning road traffic. Medical men have necessarily to do a good deal of motoring by night, and the strain of watching for a bicycle ahead without a rear light is serious. Driving at night will also be rendered easier by the numerous improvements being made all over the country to eliminate dangerous turnings, and so forth. Such improvements are urgently needed, for commercial night traffic is increasing at an amazing rate. It seems probable that before very long main roads will be as busy at night as during the day.

The proposed abolition of the speed limit of twenty miles an hour, which rarely troubles the medical man, and which in most parts of the country has been regarded by motorists and the authorities as a dead letter, is of itself not a matter of importance. Its consequences may, however, be important. Thus, whenever it is desired to prosecute hereafter it will have to be on the charge of dangerous driving. There is nothing to prevent any person, or persons, accusing a road-user of dangerous driving in circumstances in which it would be practically impossible for the motorist to disprove such a charge on his own evidence alone. The proposal to require two witnesses is in accordance with the recommendation of the Departmental Committee. It must be admitted that police evidence is sometimes prejudiced, and that even when unprejudiced the constable who gives it may be no competent judge. As cars are now being designed and built the efficiency of control varies enormously, and even experts may not always be prepared to give testimony one way or another. As a matter of practice we know also that the proclaimed policy of several benches in the country, carried out during the last score of years, has not been quite impartial. The bill it is proposed to introduce next month will probably remain in force for a good many years, and it is essential that all concerned should look carefully at the probable practical effect of the proposed changes. The clause in the bill should be so clearly worded as to make it impossible for any bench to indulge its prejudice by distorting the letter of the law. A wrongful accusation of dangerous driving may result in an innocent accused being sentenced to a term of imprisonment. Unless the bill is worded very explicitly under this head, leaving no loophole for discretion or no power of discretion on this point to departments (that is, unless it strictly and satisfactorily defines the conditions on which a prosecution may succeed), I personally am of opinion that removal of the twenty miles an hour motor car speed limit will be popular for nine days only and be regarded as a *curso* afterwards. It is the most difficult problem the Government has to face in drafting this bill. The bill will not contain any proposal to require car drivers to undergo medical examination before driving licences are granted.

#### FUTURE DEVELOPMENT OF CARS.

Mechanically, there will be many changes. There is a world-wide tendency to obtain better performance from smaller and, therefore, lower-taxed power plant. We shall see more of this when the motor show comes to be held at the end of October and the beginning of November next. It will be noted that this is a later date than that of the successful experiment at Olympia in mid-October last year. This is due to the situation in Paris, and to an old understanding between the organizations of the British and the French industries. A period will have to be put to that unwritten arrangement, however, in that it works to the detriment of the motor vehicle user and buyer, as well as to the motor manufacturer and trader, in this country. Indeed, we want, in London, not a show in the middle of October, but in the first week of that month. There will be no motor show in Scotland this year, for there were two last year.

There will be no 1,000-mile trial for standard cars in the Highlands of Scotland, nor in this country, and no Tourist Trophy car race in the Isle of Man. But there is likely to be some important racing in Dublin, for which the Royal Irish Automobile Club has been preparing for a long time.

More important in regard to the development of the car, however, is the introduction in Parliament of what a few years ago would have been regarded as fantastically impossible—namely, a private bill to permit the closing of roads for a few hours in order to conduct in the heart of England, probably in the Midlands, an international road race. Such an event could not be held this year. But the necessary Parliamentary powers are likely to be obtained this year, because it is recognized that the motor industry is a key one, and that ours is handicapped greatly by comparison with the industry on the continent of Europe and in America, where road racing is permitted. As there could be no road racing in England until 1926, and as the present small car engine limitation (1,500 c.c.m. cylinder content) will be the limit for the largest cars to be raced in the classic event in America in 1926, it seems not unlikely that such a private bill will go through. It would assist experiment and trade greatly.

From the medical man's point of view, as one who requires, to use covered types of cars, I would mention that if this essential work of experiment is carried forward under every encouragement from wise regulations, there is no reason why a 500 c.c.m. (or motor-bicycle size) engined car should not be sufficient in less than a decade to propel a four-seated saloon; this will mean an enormous saving, not only in initial cost and taxation, but also in running costs (tyre and fuel). Meantime, much more will be learned by manufacturers this year concerning lacquer finishing for cars, which can be cheap, durable, and proof against spilt petrol.

#### THE FUTURE OF FUEL.

Very important fuel experiments are being made. Of course, there is no such thing as British fuel, because benzol failed us badly last year, owing to the depression in the coal and iron industries. It cannot be produced in sufficient quantities, since it pays only to distil it as a by-product. Before a decade is out, however, we shall have something really important and quite different in the way of home-produced fuel. The talk of British petrol proves seldom to be more than the embarkation of British capital in purchasing and working oil fields in countries which, if not hostile, are at least subject to all sorts of influences from nations and interests hostile to ourselves. In the event of a national emergency such oil fields would rather need guarding than be an assured source of fuel supply to our navy. Consequently, we are living in a fool's paradise as long as we assume that we are assured of foreign oil fields. Far more important are the oil fields which exist in British territory, no matter by whom owned. At least, their outputs could and would be commandeered in emergency. But we shall not have completed the vital task until we derive a suitable motor fuel from treating raw material obtainable in these islands. At the moment I cannot state more beyond indicating that the necessary experiment will assume a very important phase by September or October next.

SATURDAY, JANUARY 3RD, 1925.

### THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.

IN the SUPPLEMENT this week is published the draft Memorandum of Evidence proposed to be given by the British Medical Association before the Royal Commission on National Health Insurance. This is one of the most important documents that has ever been put before the medical profession for its consideration. It has been the subject of prolonged thought and debate by the Insurance Acts Committee and by a large special committee containing representatives of consultants, pathologists, and others working in special branches of the profession, together with general practitioners not engaged in insurance practice. At the meeting of the Council on December 17th it was discussed, emended, and approved as a document suitable for discussion at meetings of the profession to be summoned immediately in all areas. As will be seen from the report of the proceedings of Council published in the SUPPLEMENT this week, the paragraph dealing with the question whether dependants should (subject to restrictions) be included within the scope of national insurance was retained by the Council by 25 votes to 11. As will be seen also from the list of questions appended to the draft Memorandum of Evidence, this is the first matter upon which the meetings of the profession will be invited to express an opinion.

It is true that the main proposals in the Memorandum are in substance, and often in detail, covered by resolutions which have at some time or other been passed by the Representative Body of the Association or the Conference of Local Medical and Panel Committees; but it is none the less imperative that they should be reviewed in the light of the present situation, and that any decisions upon them should be well considered by the whole profession.

The document is not a final one. It is issued as a draft merely—though a draft which represents the provisional considered judgement of those members of the profession who have had most to do with the matter with which it deals. It is now to be submitted to local meetings of the whole profession—not of insurance practitioners or members of the Association only—in the various areas, and it is hoped that all these meetings will be representative and well attended. It is hoped also that not only specialists but those general practitioners who have hitherto refrained from accepting service under the Insurance Acts will attend and freely express their opinions. Certain specific questions are to be asked at these meetings, but the whole document will be open to discussion. These meetings must be held during the present month, as answers must be ready by January 31st for consideration by a committee on February 5th, and by the Council on February 18th. Thereafter a revised memorandum will be issued to the profession;

this, in its turn, will be considered at local meetings if thought necessary; and on March 12th at a special conference of members of the Representative Body with members of the Conference of Panel Committees. This procedure should enable the Association to send the Memorandum to the Royal Commission, and to present its evidence, with complete confidence that it has behind it the full and deliberate backing of the profession as a whole. It is worth while to make sure of this even by a programme which is somewhat elaborate; any opinion so gathered and expressed must carry very great weight.

It should be remembered, however, that there is another sense in which the Memorandum is not final. It does not, and will not, represent a fixed and determined policy of the British Medical Association, or a decision which is not open to modification or revision. It is clearly to be understood that the Memorandum of Evidence to be submitted to the Royal Commission will contain merely suggestions—though suggestions of wide-reaching importance—which the profession thinks it well to place before, or even to urge upon, the Royal Commission. Some of these may not be adopted by the Commission in its report; some, even, of those adopted may not be presented to Parliament in a Government bill or embodied in any legislative Act. At a later stage, when a report is issued or when a bill is introduced, there will be time and opportunity for the profession to make its voice heard and its pressure felt with regard to any proposals actually made. This position should be borne in mind by the meetings at which the draft Memorandum is considered, but it should at the same time be remembered that it will be almost impossible later to oppose proposals substantially in the same form as suggestions made by the profession itself in its evidence.

Such is the authority and present position of the document; it is to be regarded as an attempt to present in outline a comprehensive constructive scheme for making provision for the public health along insurance lines. Proposals from any quarter which are obviously in the interest of the common health will always be received with sympathetic consideration by the medical profession, even though they may seem to conflict with professional interests and traditions; but it is of paramount importance to all, not least to the sick person, that such conflict should be avoided if at all possible, should be reduced to a minimum where it cannot be avoided altogether, and that all necessary arrangements should be so presented to practitioners as to avoid their antagonism and to secure their willing co-operation.

The scheme presented in the Memorandum, if adopted in its entirety and with all its provisos, would, it is hoped, go far to attain this desirable end. Its aim is to secure a complete medical, surgical, and maternity service for all the poorer members of the community who are unable to provide it for themselves. It seeks, while giving an impetus to preventive medicine in many ways, to preserve that individual interest in attendance and in administration which it is so desirable to perpetuate. The scheme, however, raises serious difficulties, not merely of public finance but of economic and other effects upon the profession, which need for their solution all the wisdom which the medical profession, the Royal Commission, the Ministry of Health, and Parliament can bring to bear upon them. The care with which the draft Memorandum has been prepared ought to be reflected in the earnestness and deliberation with which it is considered by every practitioner.

## IODINE IN EXOPHTHALMIC GOITRE.

"Though the waves toss we travel." The perusal of Dr. Francis R. Fraser's address, published this week, conveys a sense of progress. For fourteen years the majority of physicians have followed the advice of those who considered that iodine should not be given in Graves's disease, unheeding the assurances of some who advised them to the contrary. Now comes the convincing evidence, provided by Dr. Fraser as well as by physicians in the United States and Canada, that iodine in appropriate dosage can bring about a lowering of the basal metabolic rate and of the heart rate to a normal level, and an increase of body weight, with a striking improvement, objective and subjective, in the general condition of the patient. Though the improvement does not last it has great significance, and is of a kind which will lead in the near future to a better understanding of this remarkable malady.

In all but a small proportion of cases (5 to 10 per cent.) there is present in exophthalmic goitre, as one of its cardinal symptoms, a condition of greatly increased activity of the thyroid gland. This increased activity is associated with diffuse hypertrophy of the organ and a greatly increased discharge from it of its iodine-containing secretion. It would seem that the function of the thyroid gland is to elaborate an internal secretion containing the gland's active principle or principles, and to deliver this secretion to the circulation for distribution to the tissues in amounts proportionate to their needs. It may, perhaps, be assumed that the greater the needs the greater the discharge of this secretion. We know that iodine is indispensable to the performance of this function, and that the gland cannot go on performing it efficiently unless a sufficient amount of iodine be available to it for the elaboration and discharge of its secretion. When from any cause the supply of available iodine falls below a certain level, the demands of the tissues being normal, then the time comes when the gland's secretion is neither efficiently elaborated nor efficiently discharged. This is what happens in so-called "simple goitre," which is a state of diminished functional activity of the gland: a state which, having reached a certain degree, cannot always be rectified by correction of the iodine deficiency, although it may be set right by the injection of the gland's active principle, thyroxin. But if the supply of iodine be not at fault, and the demands for the gland's active principles increase beyond a certain point, then the organ will continue to elaborate its secretion and to discharge it into the circulation in amounts proportionate to the degree of stimulation. Here again a point may be reached when it may be assumed that there is an iodine deficiency relative to the demands of the body, and it is then that the administration of iodine in appropriate amounts will do good. It will do good by assisting the gland in the elaboration of the normal secretion itself or by bringing the gland more nearly to rest, increasing its iodine content and diminishing its blood supply. Conceivably, then, the thyroid may thereby be enabled to satisfy the demands of the body and to adjust the metabolic balance.

This, we gather, is the view taken by Dr. Fraser, who considers that in exophthalmic goitre there is "an iodine deficiency relative to the needs of the body"; and it would seem to follow that it is the outpouring of an excess of secretion deficient in iodine which exercises so profound an effect in increasing the metabolic rate. In this connexion it

is of interest to recall Kendall's conclusion that the active part of thyroxin is not the iodine it contains in such large amount (65 per cent.), but the  $\text{NH}_2\text{COOH}$  group. Why, then, does not iodine continue to do good when the patient is again subjected to the stresses and strains of modern existence, of faulty food, and of infection? Surely because the stimulus to the thyroid's hyperactivity is then of a kind beyond the power of iodine to control. Dr. Fraser mentions the fact that the administration of iodine will prevent the compensatory hypertrophy of the remainder of the normal thyroid when three-quarters of the gland has been removed; he might have added, however, that it will not prevent the hypertrophy of the remainder when nine-tenths of the gland has been removed. In the latter circumstances the stimulus to increased activity of the fragment that remains is so great that no amount of iodine will lull it to rest. The condition of the thyroid gland in Graves's disease may be compared to that of the fragments which remain after removal of the major part of the normal organ. It is under the influence of some stimulus, or of some power, so great that iodine may or may not afford the gland some rest. When it does so in the cloistered security of the hospital ward, the gland's circumstances are more akin to those of the "one-quarter fragment," and iodine then prevents its overactivity, and those symptoms of the malady which are due to the outpouring of an excess of secretion are alleviated. When, on the other hand, the patient leaves the restful shelter of the ward, and meets again the stresses of life—physical, mental, metabolic, and infectious—the gland's circumstances become more akin to those of the "one-tenth fragment," which no amount of iodine will cause to rest; while doses of iodine that formerly availed may now do harm.

Though the term "stimulation" has been used in relation to the thyroid gland's hyperactivity in Graves's disease, the impetus to the gland's disorder may, in fact, be of quite a different order: possibly of a kind, as Marine's researches on the effects of ablation of the adrenal cortex would seem to suggest, which removes some restraining influence normally exercised over the thyroid's activity. Dr. Fraser says that a great merit of the proper use of iodine in Graves's disease is that it prepares the patient for thyroidectomy; but it does more than this, for it would seem to prepare the patient for the cure of the disease. It may be suggested that in the next series of cases reported from the medical unit of St. Bartholomew's Hospital—and may this be soon—the investigation will have been carried further still, and advantage taken of this effect of iodine, in restoring the metabolic rate and the heart rate and in preventing the loss of weight, to seize the opportunity to overfeed these patients with milk, cream, wholemeal bread, green leafy vegetables, and vitamins of all kinds, so that they may gain in weight as rapidly as possible. For if, indeed, Graves's disease be due to disorder of other endocrine organs besides the thyroid—and there is not much doubt of it—then it would seem that the only way at present known to restore them to health is by appropriate food, with repose of mind and body. In this connexion, and remembering the effects of loss of function of the adrenal cortex in causing thyroid hyperactivity with depletion of the gland's iodine store, we may recall the remarkable effects of faulty food deficient in vitamins on this organ, and of the effects of bacterial products upon it.

It is said that the value of writings is proportionate

to their capacity to make readers think. Dr. Fraser's address will have this effect. Whether or not what we have here said be near to or far from the truth, it seems clear that by the recognition of this effect of iodine in Graves's disease another trench has been taken in the attack on this remarkable malady.

### CHRONIC MASTITIS AND CANCER.

No very important technical advance has taken place within the last thirty years or so in the radical treatment of cancer of the breast, and it seems as if we had come to the limits of what surgery can hope to perform in the cure of the condition. The cry, therefore, has been for earlier diagnosis, and many have hoped that, by more widespread knowledge amongst the public of the signs of the disease, cases would come to the surgeon at less advanced stages, so that radical operations might achieve an enhanced percentage of permanent cures. It is unwise to assume because a growth is very small, or has only been noticed for a short time, that a more restricted operation than usual will be effective, for the lymphatic dissemination in such cases may be surprisingly extensive, and probably most surgeons practise a wide removal, no matter how early the cancer may seem to be. Whether any method of popular instruction or propaganda will be successful in inducing the public to seek medical advice more opportunely is a question upon which opinions may differ, and the surgeon has to deal with the disease in such a stage as it comes to him, and not as he would like it to be. There can be little doubt that, owing to the equivocal nature of the early manifestations, an expectant policy is adopted far too often, with disastrous results. This is hardly the fault of the general practitioner, who is as eager as his surgical colleague to read the signs aright. Once a definite tumour is detected there should be no delay in having recourse to surgery, and probably in the vast majority of cases no undue delay occurs.

There are many who are convinced that future advance in the treatment of cancer of the breast must lie in the exploration of the mammary lesions before palpable growth formation has taken place. The surgeon frequently comes across borderland cases where he cannot be certain of the nature of the condition—it may be simple or it may be malignant. And the practice differs with different surgeons. Some treat these as if they were frankly malignant, and perform the complete radical operation. Such a proceeding, as it leaves nothing to chance, may be condoned even if, in the majority of instances, it is unnecessary. Others remove the mammary gland alone, and submit the specimen to the pathologist for examination, being guided as to whether a subsequent operation is desirable or not by the result of the pathologist's findings. Probably this is the most satisfactory and most frequently adopted routine. Others, again, remove a small portion merely and have it examined there and then by frozen section, arresting the proceedings until the verdict is given. Granting that in the hands of an expert reliable indications may not infrequently be obtained, the histological pictures so revealed are always too crude for absolutely certain interpretation, and even with properly prepared paraffin sections the most experienced pathologists are sometimes unable to give a verdict one way or the other. This is not surprising, as there is no sharp demarcation between the simple and the malignant. If we could pick out with any degree of certainty or even probability the precancerous con-

ditions—that is, such as if left alone would inevitably become cancerous—surgical treatment would be infinitely more effective; but at present neither the surgeon nor the pathologist is in a position to do so. There are, to be sure, those who maintain that the condition generally called chronic mastitis is a precursor of, and frequently develops into, carcinoma; on the other hand, there are surgeons of considerable experience who hold that carcinoma is no more liable to arise in a breast affected by mastitis than in a mammary gland not so affected; and according to their opinions they remove the organ entirely, or only a portion of it, or even they may leave it untouched.

The term "chronic mastitis" is unsatisfactory, and a host of other names have been suggested; but still it has been sanctified by use, and to the clinician it connotes a fairly definite condition. To the pathologist, however, it is a very nebulous term, embracing practically every lesion which is neither an acute inflammation nor a true neoplasm, and he is further handicapped by the impossibility of choosing a standard for the normal breast of older women. In this field Sir Lenthal Cheate (whose address appears in this issue at page 5) has laboured for several years, to the advantage both of the surgeon and the pathologist. By his methods of large sections he has clearly demonstrated how extensive the pathological changes are in a breast which is the seat of cancer. In the same organ there may be all degrees of hyperplasia of the epithelium right up to malignant neoplasia. It is to these concomitant features, which were not realized until Sir Lenthal pointed them out, that one must look for a sure indication of the precancerous states, and it is interesting to note that he has found the same features in some cases that were considered to be chronic mastitis. If we understand him rightly, he does not insist that chronic mastitis is liable to become cancer, but that within the group of lesions to which that term has been applied there are a certain number which are essentially neoplastic. Whether these can be separated off by clinical diagnostic methods alone is doubtful, but it is only by the careful study of the "mazoplasia" that the pathologist may hope to gain a clearer appreciation of the nature of the precancerous stages.

### THE YOUNGER UNIVERSITIES.

Of the universities founded in England during the nineteenth century—a not inconsiderable achievement of that much maligned epoch—the majority grew out of or were preceded by a school of medicine. This is true to some extent even of London, though the foundation of that university was really a protest against the Test Acts by which at that time admission to the Universities of Oxford and Cambridge was limited. Durham is hardly an exception, nor is Sheffield, though before the institution of the university there the medical school was small. Manchester, Liverpool, and Bristol are not exceptions, nor is Leeds, and Sir Berkeley Moynihan has done well in his address, delivered during the jubilee celebrations, to recall some of the great achievements of the great men of the Leeds school. Their names we need not repeat; are they not to be read in the address published at page 36? They seem all to have been men of a certain sturdiness of mind and independence of judgement, a tradition which has been carried down to the present day. The "Heydays" of Leeds surgery began in the eighteenth century, and the first William Hey had the courage to challenge the supremacy of London, which was then the metropolis of surgery, owing

largely to the work of John Hunter's pupils, among whom, it is to be remembered, William Hey himself was numbered. Whether or not the late Mr. Pridgin Teale's boast that the Leeds Infirmary was the first hospital in England to put Listerian methods to the test is well founded (we fancy University College Hospital, London, must have run it very close), it is certain that some of the surgeons in Leeds very early appreciated the importance of Lister's theory and practice. One of Mr. Teale's contemporaries of whom mention is made in the address—Mr. C. G. Wheelhouse, a surgeon of much ingenuity and resource—was a strong friend of the British Medical Association; he was Chairman of its Council for three years (1881-83), and its President when it held its Annual Meeting at Leeds in 1889. The Leeds School of Medicine was founded in 1831, though teaching had been given in the town at an earlier date. The Yorkshire College was established as a college of science in 1874, and the two institutions were united in 1884. The united body formed a part of the Victoria University from 1887 to 1904, when the University of Leeds was founded by Royal Charter. It now has many faculties—arts, science, technology, engineering, commerce, and many subsidiary faculties—but the School of Medicine still maintains itself as one of the chief, as it is the oldest, of its departments. The laboratories of the University are bewildering in number, and not a few of them are related to the many industries of the industrial region of which Leeds is the centre. It attracts students from abroad, and altogether the number of those working for its degrees or diplomas exceeds a thousand.

#### A LISTERIAN ORATION OF CANADA.

LISTER is one of the immortals. Lord Rosebery many years ago devoted to the memory of Robert Burns one of the finest orations he ever delivered. In the course of it he conjured up a centennial roll-call of the men who have been regarded by their contemporaries as secure of immortality, and he speculated as to how many of these would, after hundred-year intervals, fail to answer to their names. But as regards his own hero, the ploughman poet, he prophesied that the *Adsum!* of Burns would sound clear and strong all down through the coming centuries. So it will be with the name of Joseph Lister in the list of benefactors of mankind. In the ranks of medicine, no more than Harvey or John Hunter does he need an annual oration to perpetuate his memory. But just as the pride and gratitude of the profession to which they belonged have led to the commemoration of these great men, so it is appropriate that Lister's services to humanity should be made the occasion of public oratory. Influenced by such considerations, there has been formed within the Canadian Medical Association a Lister Memorial Club, and Dr. John Stewart of Halifax, who was one of Lister's dresser-clerks, and who accompanied the master when he left Edinburgh for King's College, London, was appointed by the Council of the association to deliver the first Listerian Oration. The occasion was the annual meeting of the association at Ottawa, and the date June 18th, 1924. The oration has now been published as a special number of the Association's *Journal*, with an appropriate and appreciative foreword by Dr. A. D. Blackader. It constitutes a most suitable introduction to what will no doubt be a long series of deliverances on surgical work which would never have been done, and surgical problems which could never have arisen, had it not been for Lister. The orator begins with a brief account of his hero's early days, touches on his holiday studies in natural history and chemistry, his education in surgery at University College, his going to Edinburgh with the intention to stay there for a few weeks to see the practice of Professor Syme, and how that stay was prolonged for nearly seven years, his appointment to the Glasgow chair of surgery in 1860, his succession

to Syme in Edinburgh in 1869, his visits to the Continent and America, his transfer to the professorship left vacant by the death of Sir William Fergusson at King's College in 1877, and his gradual triumph over difficulties in the world-wide acknowledgement of the greatness of his work. But it is impossible to follow Dr. Stewart through his enthralling story, which combines personal reminiscences with sketches of the later events in Lister's career, and displays not only the qualities of the surgical scientist, but the high Christian character and personal distinction of the man. Dr. Stewart has indeed worthily inaugurated what will now become the stated annual celebrations of the great surgeon with whom he had the good fortune to be so closely in contact both as master and friend.

#### ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

IN the days of the Local Government Board medical officers of health were accustomed to receive at the end of each year a memorandum from the medical officer of the Board with respect to their annual reports. The memorandum was couched in very general terms, although certain subjects were mentioned as to which it was desirable that detailed information should be given. During the years of the war the Board suggested that, having regard to the necessity for strict economy in the use of paper and in demands on printing establishments, the annual reports should be confined to statistical records and urgent matters which had affected the public health during the year. On the termination of the war the whole question of these reports was considered by the Ministry of Health, and, after conference with the Society of Medical Officers of Health in 1921, it was decided that a full and detailed report would only be required normally once in five years. In a circular (No. 540) as to the contents and arrangement of the annual reports of medical officers of health, issued on December 18th last by the Ministry of Health, it is intimated that the report for 1925 will be of this detailed character, or, as it is described, a "survey report." In this document the medical officer of health will be expected to deal comprehensively with the measure of progress made in the area during the preceding five years in the improvement of public health; with the extent and character of the changes made during that period in the public health services of the area; and with any further action of importance in the organization or development of public health services contemplated by the local authority or considered desirable by the medical officer of health. The report for 1924 is to be an ordinary report on the lines laid down by the Ministry in circulars issued annually during the past three years. The current circular is a revised edition of its predecessors, though the alterations and additions are, for the most part, not of primary importance. In paragraph 3 it is made clear that information should be given with regard to maternity and child welfare schemes and schemes for the treatment of tuberculosis or venereal diseases, and not merely with respect to centres or institutions. The Registrar-General will continue to supply, as he first did for 1923, information about the number of cases of certain infectious diseases notified during the year. Information is also asked for now with regard to the administration of the Milk (Special Designations) Order and the Condensed and Dried Milk Regulations. An important alteration has been made in the housing section of the appendix. Details are asked for as to the "Number of dwelling-houses which were rendered fit after service of formal notices" under Section 28 of the Housing, Town Planning, etc., Act, 1919, and of the "Number of dwelling-houses in which defects were remedied after service of formal notices" under Public Health Acts. The words in italics are introduced for the first time this year, and should assist in making the records of medical officers of

health more comparable than has hitherto been the case. A medical officer of health is required by the Factory and Workshop Act, 1901, to report annually on certain matters connected with the administration of the Act, and until 1920 the Factory Department of the Home Office supplied medical officers of health with a form (572) containing tables for their guidance in presenting information regarding inspections, formal notices, prosecutions, and defects found and remedied. This form has been reissued this year. A summary of these tables, which it may be expected will appear in due course in the report of H.M. Chief Inspector of Factories, will serve to emphasize the important position held by medical officers of health with respect to the sanitary conditions of factories, workshops, and workplaces.

#### THE DANGERS OF VERONAL AND ITS DERIVATIVES.

At an inquest held recently by the deputy coroner for West London with regard to the death of a lady, aged 41, Mr. John Webster gave evidence to the effect that death was due to veronal poisoning. Sir William Wilcox, who had seen the patient before death, said that the danger of the veronal group of poisons was not fully realized. This class of drugs ought to be made subject to the restrictions of the Dangerous Drugs Act; the number of deaths was greater than the Registrar-General's returns showed. A craving for this class of drugs arose if they were taken habitually, and a very definite form of mental deficiency, accompanied by delusions and inarticulate speech, might be produced. After a very large dose of veronal pneumonia supervened within about twelve hours. This is a point, we may observe, to which Sir William Wilcox called attention in a paper read at the International Medical Congress in London in 1913. At its meeting last month the Council of the British Medical Association had before it a communication from the Home Office stating that the Home Secretary had under consideration the advisability of bringing under the Dangerous Drugs Act the group of drugs derived from barbituric acid (veronal, propional, medinal, luminal, dial, etc.). A small informal departmental conference, attended by Sir William Wilcox and representatives of the Royal College of Physicians, held recently, suggested, we understand, that in the event of the barbitone group of drugs being brought under the Act the extent of the control should be limited to preventing their sale to the public except on the prescription of a duly qualified medical practitioner. The Home Secretary invited the Association to send representatives to a conference to be held this month to consider a draft Order in Council and draft regulations. The Council accepted the invitation, and nominated Mr. E. B. Turner, Chairman of the Medico-Political Committee, Dr. J. W. Bone, a member of that Committee who has given special attention to the Dangerous Drugs Act, and the Medical Secretary, to represent the Association at the conference. We publish elsewhere (p. 56) a pathetic letter from a member of the medical profession who has recently had a distressing experience of allonal.

#### AUTO-HAEMOTHERAPY AND SKIN DISEASES.

TRANSFUSION of blood (hetero-haemotherapy), which consists of the injection of the blood of one subject into another, has been known to medicine for nearly three centuries. Auto-haemotherapy, however, which is the reinjection of a certain quantity of the patient's own blood into himself, is more modern. Spiethoff of Jena first had the idea of treating certain dermatoses by the injection of the patient's own serum. It was later suggested by the French dermatologist Rarant that blood should be used instead of serum. Hebrant, Antoine, and Liégeois<sup>1</sup> have recently recorded the results of some interesting experiments on the skin diseases

of dogs conducted along these lines. Their technique consists in the aspiration of 1 c.cm. of citrate solution into a 10 c.cm. hypodermic syringe, which is then filled with blood drawn from the jugular vein. This citrated blood is injected subcutaneously in the costal region, or intra-arterially in the gluteal region. They do not attempt to explain fully the rationale of their method, but they think that it may be anti-anaphylactic in nature. Every anaphylactic reaction is the result of a previous sensibilization. In the case of a reaction with a cutaneous localization the toxic substances reabsorbed in small doses have the effect of the preliminary injections. Normally these reabsorbed doses are dealt with by the liver and other organs. When their functions are in abeyance an anaphylactic shock is set up, which, although far removed from the skin, has nevertheless cutaneous localizations (vaso-dilatation, urticaria, pruritus). If this is so, auto-haemotherapy may be considered to be an anti-anaphylactic method. Hebrant and his associates conceive this action as a form of protein therapy, depending on the production of a protein shock (without preliminary sensibilization), the manifestations of which are confined to the blood stream. The parenteral introduction of a non-specific protein brings about a physical modification of the complex blood colloid (colloidoeclassia). The reinjected blood has not the same physical nature as it had before being drawn: its mixture with the citrate solution, contact with the walls of the syringe, and cooling, have rendered it a different colloid as compared with the circulating blood, which is thus returned to its normal state. This supposition seems to be pure hypothesis, and further work is needed for confirmation. These workers claim to have treated successfully a number of cases of eczema, alopecia, and pruritus by this method. They conclude that auto-haemotherapy is indicated in the case of all non-toxic and non-parasitic pruritus, and that it is a valuable adjuvant in chronic, but not in acute, eczemas in the dog. Panisset and Verge<sup>2</sup> had previously arrived at similar conclusions. On the other hand, several observers have found that this new therapeutic measure has little or no effect, so further developments will be awaited with interest.

#### ENZOÖTIC JAUNDICE IN DOGS.

CANINE enzoötic jaundice is a very common disease in this country, as elsewhere, and causes considerable losses to dog breeders and masters of hounds. Until recently comparatively little was known about it, and, indeed, most people considered that it was merely a variety of distemper. It is characterized by the production of a large amount of haemoglobin in solution, with the consequent clinical picture of jaundice. Other symptoms are vague, sometimes there are none, and the lesions are far from constant; accordingly diagnosis is very difficult. In the last few weeks, however, Okell, Dalling, and Pugh have been able to demonstrate that the disease, like that sometimes, in man, called Weil's disease, is caused by *Leptospira icterohaemorrhagiae*, a spirochaete normally attacking rats. Presumably the disease is transmitted to dogs by the bite of infected rats—a presumption which is supported by the fact that jaundice is commonest in pups of hunting and terrier breeds. The disease in man has excited the interest of many workers, and a serum has been prepared from horses which has been found to exercise a considerable prophylactic and curative action in dogs. So far no human cases have been found associated with the disease in the dog, but the possibility of infection of man from this source cannot be altogether ignored. The connexion between enzoötic jaundice and canine distemper is a very vexed question. It is often very difficult to separate them on clinical grounds, and hitherto laboratory diagnosis has not been possible. The opinion is gradually gaining ground

<sup>1</sup> Ann. Méd. Vét., 1924, pp. 305-12.

<sup>2</sup> Rev. Gén. Méd. Vét., October, 1923.

that distemper is not a single clinical entity at all, but may consist of a number of different protozoal and bacteriological diseases. The whole question, however, becomes more complicated as fresh facts are discovered. It will be remembered that the Medical Research Council undertook the study of distemper, not only to help to elucidate the canine problem, but in order to accumulate data for the study of human infections suspected to be due to so-called ultramicroscopic virus. The disease is one of such importance that we hope the lack of immediate success indicated in the interim report of last spring will not discourage those engaged in the inquiry.

#### TUBERCULOSIS REGULATIONS.

THE compulsory notification to a medical officer of health of cases of tuberculosis came into force in England and Wales in 1909 under regulations made by the Local Government Board, the application of which was limited to cases of pulmonary tuberculosis occurring among Poor Law patients. A few years later this limitation was removed, and since February 1st, 1913, it has been the statutory duty of every medical practitioner to forward to the medical officer of health certain specified particulars of all cases of tuberculosis—pulmonary and non-pulmonary—attended by him. The medical officer of health is required to keep a register of the cases notified to him, and to take steps to make it a correct record of the number of persons in his district who are suffering from tuberculosis. Notification certificates wrongly addressed to him must be sent by him to the appropriate district, and at least once every three months he must revise the register by erasing the names of deceased persons and of those who have removed from his district. In many districts difficulties have arisen in keeping a sufficiently correct register to render it of much use for statistical purposes. On the one hand, a certain proportion of cases are not notified and so do not get on the register, and, on the other hand, names are left on the register which should be expunged. In the first category are patients attending a dispensary who escape notification because the tuberculosis officer thinks a notification certificate has already been transmitted. In a circular (549) recently addressed to sanitary authorities in England by the Ministry of Health the opinion is expressed that a tuberculosis officer should immediately notify each case in which he diagnoses tuberculosis unless he ascertains definitely that a practitioner has notified, or will notify, the case. In the second category are those who have died or who have removed from the district, and those in whom the diagnosis of tuberculosis has not been established or are said to have been cured. The name of a deceased person may be kept on the register because, quite legitimately, his death has been certified as due to some other cause. With a view to minimizing this source of error the Ministry of Health, in a circular (549A) recently addressed to county councils and tuberculosis joint committees in England, suggests to those bodies that their medical officers should communicate to medical officers of health any information they may have as to deaths or removals. As regards cases the diagnosis of which has not been established, the Ministry considers that no case should be removed from the register except with the assent of the notifying practitioner unless he is no longer available for consultation. The views of the Ministry as to cured cases are important. They are "that the removal of a case from the register as 'cured' is justified in pulmonary cases in which for a period of five years there have been no symptoms of tuberculosis and no signs of tuberculous disease, except such as are compatible with a completely healed lesion, and sputum, if present, has been free from tubercle bacilli; and in non-pulmonary cases in which three years have elapsed without any signs or

symptoms of active disease." In order still further to assist in an accurate compilation of the tuberculosis register the Public Health (Tuberculosis) Regulations, 1924 (England and Wales), have been made by the Minister of Health, and they came into operation on January 1st, 1925. They require the medical officer of health to furnish the county medical officer of health at the end of every quarter with a statement showing the number of cases, distinguishing between males and females and pulmonary and non-pulmonary cases, on the register at the commencement of the quarter, the number notified and removed from the register during the quarter, and the number remaining on the register at the end of the quarter. As regards the removals from the register, the names and addresses of those removed must be given, and the reason for the removal.

#### THE WALLER MEMORIAL.

AUGUSTUS WALLER died in March, 1922, and his wife, whose fatal illness began before his sudden death, did not long survive him. As Sir Edward Sharpey-Schafer said at the meeting to inaugurate the memorial fund, Waller's physiological work was extraordinarily original and always accurate, even when working over new ground; his wife was a perfect helpmeet, taking the most lively interest in his work and habitually acting as one of his assistants. A desire to commemorate their lives arose in the minds of physiologists and their many friends, and it was natural to propose that the memorial should be associated with the London School of Medicine for Women, for Waller had been at one time lecturer in physiology there, and his wife was first a student, then demonstrator, and later a member of its council until her death. A sum of £2,000 has been subscribed by 206 donors, and has been paid over to the council of the school to invest, and to apply the interest for purposes of scientific research, to which both Waller and his wife owed lifelong devotion. Waller was for nineteen years lecturer in physiology at St. Mary's Hospital Medical School, London, and a further sum of about £105 has been subscribed towards a memorial to Waller in that school, to take the form of a Waller research room. As the larger scheme has clearly appealed more strongly to the friends of Dr. and Mrs. Waller, it may be necessary to reconsider the proposal with regard to St. Mary's Hospital Medical School, and in that event the donors will be consulted as to the best method of applying the money they have subscribed.

#### THE TEAM SYSTEM IN PHYSICAL TRAINING.

THE Board of Education has issued a circular<sup>1</sup> containing suggestions intended to supplement the notes on the "team system" contained in Appendix B of the Board's Syllabus of Physical Training, 1919. The team system is the name given to a method of organizing a class in teams, which work together under their leaders in games and exercises, and compete with other teams. Physical training through team work combines healthy individual exercises with the education of the children to become members of society. Organized team games provide an outlet for the spirit of competition and an opportunity for correcting the extravagance of individual competition by subordinating it to the social spirit. In order that competition may have a social value it should have a co-operative basis, and the competing unit should, therefore, be the team and not the individual. The quality rather than the actual result of each competitor's efforts becomes the standard of value. The less capable are encouraged by the thought that their efforts are of service to the remainder of the team, while the more highly endowed realize their responsibility to give of their best for the common good. Suggestions are given for the introduction of the team system into all but the smallest rural schools.

## THE CONTRIBUTIONS OF LEEDS TO SURGERY.

AN ADDRESS DELIVERED AT THE COMING OF AGE OF THE  
UNIVERSITY OF LEEDS ON DECEMBER 8TH, 1924,

BY

SIR BERKELEY MOYNIHAN, Bt., LL.D.

The craft of surgery is as old as mankind. The earliest human remains show that the art of the surgeon had been practised upon them. Among the hoary superstitions by which men have always been beguiled, that which is concerned with belief in the "possession" of the human body and mind by demons is perhaps the most interesting. The ancient rites practised for exorcism have survived to the present day. In the *Yorkshire Evening Post* of August of this year an account appeared of the casting out of devils from a young girl in Tuscany. For the relief of this malady of "possession" the aid of the surgeon was not infrequently invoked in prehistoric times. Wherever skulls of the Neolithic period have been discovered, openings made by the trepan have been found in them. The apertures are not due to accidents after death, for the shape of the fragments removed is always similar, the parts of the skull in which they are found are often the same, and the edges of the gap show that the discs of bone must have been removed during life, for healing had clearly taken place. The piece of bone removed in this way was worn as an amulet. It is interesting to learn that the operation of trepanning is still practised in the ancient way, to permit the escape of evil spirits confined within the skull, by the natives of New Ireland, to the east of New Guinea. Of no art, then, are there more ancient records than of the art of surgery.

Many of the diseases for which the aid of surgery now is asked are as old as human history. In the bodies of the mummies found in Egypt evidences of gall stones, of appendicitis, of tuberculous disease of the bones, including the spine, of sarcoma of bone, are plain to be seen.

The science and the art of surgery owe their twin birth to Hippocrates, under the fertile inspiration of the Socratic philosophy. His power of accurate observation, combined with ingenuity and integrity in the exercise of the faculty of reason, have rarely, if ever, been surpassed by any man. So vast was the range of his observation, and so amazingly accurate his comments, that the minds of many generations of his successors were fully occupied in the consideration of the intellectual legacy he had bequeathed to them.

It was not until centuries later that Galen, a vain, ambitious, garrulous, and rather quarrelsome man, brought experiment to bear upon the problems of physiology and of medicine. As Hippocrates was the parent of inductive reasoning, so was Galen of the deductive method. Galen's experiments were, of course, confined to the bodies of animals, and it was by "analogy" that he applied their results to the bodies of men. Though he was the first of experimenters, he asserted that speculation should lead experience. If his reasoned conclusions were not supported by experiment it was because the experiment was fallacious. Yet no man has dominated the mind of the world for so long a stretch of time as Galen. For 1,500 years his authority was unchallenged. Men sought for all truth, and for all experience, not in the study of the living patient, but in the writings of this dead philosopher. The Fathers of the Church have never had their writings more implicitly accepted, their doctrines more loyally observed, and their errors more confidently believed, than these Fathers of Medicine, Hippocrates and Galen. For nearly 1,500 years the writers on medicine preserved with reverence the old tradition and the ancient knowledge; they discussed every device and at interminable length they elaborated the meanings of the old scriptures; they tortured new meanings out of old phrases; they were diligent in dressing old words anew, and their scholarship was judged by their ingenuity and infinite prolixity in so doing.

From the long slumber of nearly 1,500 years medicine was awakened by William Harvey. The influence of great teachers in inspiring great students was never more happily

shown than when the great anatomist Fabricius became the lodestone that attracted Harvey to Padua. The discovery of the circulation of the blood, a discovery on the very edge of which so many men had trembled, is the great glory of English medicine. But it was a discovery made possible by the example and the encouragement of a great teacher. Harvey was often wearied and despondent. He found the tasks upon which he laboured so arduous and full of difficulties that he was tempted to think with Fracastorius that the motion of the heart was only to be comprehended by God. The discovery has been claimed for many men and many countries. But a strict examination of the evidence leaves no doubt that Harvey's claim is now beyond dispute. The unhappy Serretius had recognized the existence of the pulmonary circulation, and was in consequence burned as a heretic, with all his works, by Calvin, at Geneva in 1553. To controvert the teaching of Hippocrates and Galen was not error only, it was heresy. It required a rare and reckless courage for Henry of Mondeville to say that "God did not surely exhaust all His own creative power in making Galen."

Harvey, Galileo, Bacon, Gilbert, physician to Queen Elizabeth, confirmed in their several ways the value of experiment in research. But the method was to find, as yet, no place in surgery, for the foundations of surgery were not yet laid. No knowledge existed as to the nature of the diseases by which man was so grievously afflicted. The morbid appearances of the organs, the processes by which they were attacked and laid waste, were almost unknown. It is due to Morgagni, and to our own John Hunter, that this defect was made good. The science of pathological anatomy was founded by them, and their investigations were carried so far that, nearly a century and a half later, we may still read their works with advantage.

The first of the surgeons in Leeds was a pupil of John Hunter. William Hey was one of the founders of the Leeds General Infirmary in the year 1767. At the age of 14 he had been apprenticed to Mr. Dawson, a surgeon of Leeds, much against his own inclination, for he wished to follow the sea. He studied at St. George's Hospital, and so proper was his conduct, so high his intelligence, and so assured his future, that a gentleman offered him his daughter in marriage. Hey, it is said, gave "the same prolonged consideration to this suggestion as he was accustomed to give to all matters of importance," and declined the offer. When he returned to Leeds to practise surgery the outlook seemed unpromising. Mr. Lawman, the chief surgeon of Leeds, had only once operated for the stone, and had only once amputated a limb. In the year 1767 Hey performed each of these operations four times. In the years 1800, 1803, 1805, and 1809—the Leeds General Infirmary being, as now and always, in want of funds—he gave anatomical demonstrations upon the bodies of criminals, and handed the funds over to the Infirmary. As we look back and endeavour to measure the value of the work done by the pupils of Hunter, we may safely claim that Hey was not inferior to any of them, not even to Abernethy or to Astley Cooper, the handsomest and most popular surgeon of his time. London was then the metropolis of surgery. Hey was the first to challenge this supremacy.

The eponymous contributions of William Hey to anatomy and to surgery outnumber those of any surgeon. There are two "Hey's amputations," one in the foot and one in the leg; a "Hey's ligament"; "Hey's hernia"; "Hey's internal derangement of the knee"; the "fungus haematodes of Hey"; and "Hey's saws" are in use to this day. Hey founded a dynasty of surgeons. His son William Hey, and his grandsons William Hey, Samuel Hey, and Edward Atkinson, who served in the Crimea, were all surgeons to the Leeds General Infirmary. His great-grandson, Dr. Wawn of Ilkley, was a student of the school. Hey was a close friend of Priestley, and their amity was undisturbed by their not infrequent theological controversies. Hey died in 1819 of diverticulitis of the colon.

The names of two great surgeons of the days contemporary with the "Heydays" of Leeds surgery have survived. Samuel Smith (1790-1867) was held in most affectionate remembrance by Mr. Teale and Mr. Jessop, who regarded him as the most "common-sense man" they encountered in their younger days. He was surgeon to the Infirmary for forty-five years, in general practice; and he

lectured for thirty-five years on midwifery at the hour of 7 a.m. A widow, anxious as to the engagement of her only daughter to a youth with whom she was unacquainted, took counsel with Sam Smith, and confessed her ignorance of the tests to which the youth should be submitted. "Invite him to breakfast," said Sam Smith, "and if he eats a good meal you may safely allow him to marry your daughter." A letter is extant in which he invites a colleague to breakfast at 5.30 a.m. He was a pioneer in the operation of excision of the astragalus; and his portrait in the board room of the Infirmary will keep this claim for ever before our eyes. He seems to have been every man's friend.

Thomas P. Teale (1801-1867) was the son of a successful Leeds practitioner. He was trained at the United Borough Hospitals, and qualified in 1823. He was elected surgeon to the Leeds Dispensary in 1824, and to the Leeds General Infirmary in 1833. He served for thirty-one years. Like William Hey the first, he had lost one eye in childhood. He excelled in the operations for stone, lithotomy as well as lithotomy, and in plastic surgery. He was active in inquiry and research, and he was eager in pursuit of new plans of treatment. He enriched our museum. He was zoologist as well as geologist, writing lengthy papers on each subject; and salmon fishing was the recreation in which he, like many other members of our staff, excelled. He invented a new method of amputation, which to this day is known as "Teale's amputation," and is practised more often than its merits deserve. The reasons which made it so successful in the old days hold good no longer; and the long anterior flap is wasteful. Teale also wrote a treatise on hernia, a sound textbook much quoted in its day. He was a Fellow of the Royal Society, and one of the founders of the Leeds Philosophical and Literary Society.

Throughout all these centuries, from Hippocrates to Hunter and to Hey, the lot of the individual patient was, however, not very greatly improved. More, far more, was known of the causes, symptoms, and morbid processes of disease, but in direct consequence of all this little advantage came to the patient. An operation practised for the relief of any disease was attended by a mortality almost prohibitive, and by a delirium of pain that only the stoniest hearts could face unflinchingly. Anaesthesia, whose merciful discovery we owe to Morton of Boston (October 26th, 1846), robbed operations of their most menacing terrors, but many survived the operation only to perish quickly from its effects. And the effects were terrible beyond belief. A visitor to Paris during the Crimean war wrote: "We can recognize at a distance a surgical hospital owing to the stench of the human putridity it contains." Bell of Edinburgh spoke of a hospital as a "house of death." The death rate from all surgical conditions was very high: the simplest procedures, carried out with superb craftsmanship, became deadly because of that infection in the wounds which nothing seemed able to prevent or to control. And then Lister came and all was changed.

It is perhaps impossible for the surgeons of to-day to realize the magnitude of the change that has come over surgery because of the work of this one man. Operations which were attended by a prohibitive mortality are now performed without a thought of mischance; and operations then beyond the power of the most reckless to imagine are matters now of everyday routine. Lister made the old operations safe and the new ones possible. And I have made the claim for him which understates the truth, that he has been the means of saving more lives than all the wars of all the ages have sacrificed. Leeds at this moment, too, had its standard-bearer in the new great fight that was to be waged against diseases hitherto unassailable. Thomas Spencer Wells (1818-1897) was a student of the Leeds School of Medicine, acted as an unqualified assistant to a parish surgeon, and attended the lectures of William Hey the second and the elder T. P. Teale. He had been apprenticed to Dr. Michael Thomas Sadler of Barnsley, nephew of the distinguished author of that treatise, *On the Law of Population*, which attracted the attention of Macaulay. After qualifying, Spencer Wells served in the navy until the age of 30, when he retired and went to London to practise. In the year 1854 he assisted Baker

Brown to perform the operation of ovariectomy; both were discouraged by the death of the patient. In January, 1855, Spencer Wells sailed for the Crimea, and there learnt that "a man's abdominal walls might be lacerated by fragments of shell, his intestines protrude for hours till they were covered by dirt, and yet that after careful cleansing of the cavity and accurate closing of the wounds complete recovery was possible."

In 1856 Spencer Wells returned to London, and in December, 1857, attempted his first ovariectomy; the patient died. The second patient, operated upon in February, 1858, happily survived, and so the way was opened for the intrepid advance which Spencer Wells was eager to make. His success was almost incredible, having regard to the fact that his early operations were performed before Lister's work began, and that the opposition of his colleagues was unrelenting. The moral courage required to persist in his efforts may be inferred from the opinion expressed by the most influential medical review of the day, that the operation was one which, "though it may excite the astonishment of the vulgar, calls neither for the knowledge of the anatomist nor the skill of the surgeon," and that "when-ever an operation was performed so fearful in its nature, often so immediately fatal in its results, a fundamental principle of medical morality is outraged." Wells, undismayed, pursued his course, telling with perfect frankness the story of his successes, and of his failures, and at last led the medical profession to recognize the value of his work. He was the great pioneer in all the stupendous advance that the art of surgery has made in the last fifty years. Ovariectomy being made safe, other abdominal operations were attempted, and error in diagnosis was not without its value. Spencer Wells, in operating upon a case of "ovarian cyst," found that the fluid was free in a peritoneal cavity whose walls were studded with tubercles. And the surgical treatment of tuberculous peritonitis was inaugurated at that moment. In operating in 1887 upon a young girl, jaundiced from her birth, for the removal of a "fibroid tumour of the uterus," the tumour was recognized as an enlarged spleen. With the quality so characteristic of Leeds surgery of meeting a difficult situation with courage and ready resource, the spleen was removed. The jaundice soon disappeared, and a new chapter in our knowledge of splenic disease was opened, and for the first time a patient suffering from haemolytic jaundice was cured.

The minds of men are too often repelled by novelty. It is perhaps not so much the new thing as the new-fangled thing which excites opposition. And of opposition Lister received full measure. His theory and his practice alike were new-fangled, and the assaults upon both were vicious and unrelenting. The attitude taken by the surgeons of Leeds is interesting. The older men were sceptical as to the truth of Lister's teaching: the younger discussed it with enthusiasm, tested it, proved it, and applied it. The fierce opponent to it was Thomas Nunneley (1809-1870). After he was qualified Nunneley went to Paris "to increase his professional knowledge." On his return he applied for the post of house-surgeon at the Leeds General Infirmary, and was not elected. He realized at this time that there was an opportunity for the practice of ophthalmic surgery in Leeds, and he applied for, and obtained, the post of surgeon at the Eyo Hospital, and for twenty years worked in Leeds with "eminent success." Then in 1864 he was appointed surgeon to the Leeds General Infirmary. His most important work was *An Essay on Erysipelas*, published in 1831, and again in 1841. In 1869 he delivered the annual address in surgery before the British Medical Association. The address occupies thirteen pages of the JOURNAL. It is well written in a vigorous, graceful, if rather ornate, style; but it contains a bitter attack on the methods of Lister. Allusion was made to the practice of his colleagues and their application of the principles of the antiseptic treatment, and Nunneley asserted that "for every successful case that they could show with it, he could show as good a one without it." He then went on to say that lately the omission of the treatment, even in large operations, had been more and more frequent, until its use had become the exception instead of the rule—

a change which, had "any marked benefit resulted therefrom, most certainly would not have happened." Now this was carefully calculated to wound the members of the staff. For, as Mr. Pridgin Teale always assured me, the Leeds Infirmary was the first hospital in England to put the practice of Lister to the test; and the improved results from it, even in its crudest forms, convinced the staff of the accuracy of the hypothesis upon which it was based. A flat denial of Mr. Nunneley's statement followed. A letter from Mr. Teale to Mr. Lister was published three weeks later in which it was categorically stated that "Mr. Nunneley was in no sense justified in making such a statement; we still use and have as much confidence as ever in antiseptic treatment," and that "any want of success in our practice may fairly be attributed to imperfections in carrying out the rules." Mr. Nunneley, though urged by his friend to retract, made no reply. Nunneley was the author of an operation for cancer of the tongue which bore his name (BRITISH MEDICAL JOURNAL, 1866, ii, 493). It was certainly the quickest, neatest, and safest of all the operations practised in that day. My father-in-law, Mr. Jessop, was apprenticed to Mr. Nunneley. I have heard much of those times in many talks. Mr. Nunneley was a man not without ability of the ready-witted kind. It is interesting to remember that he appeared in defence of Palmer, found guilty of poisoning Cook by strychnine in 1856.

His son, John Nunneley, was ophthalmic surgeon to the Leeds General Infirmary, and in his earlier days demonstrator of anatomy at the school. Infinite reiteration was the secret of his success as a teacher. I can still hear him say, "The cribriform fascia, gentlemen, the cribriform fascia is the deep layer, the deep layer of the superficial fascia; the deep layer is the cribriform fascia, the deep layer of the superficial fascia." He was a silent, reserved man, and an excellent chief for whom to work. I was his dresser and enjoyed my days with him, and learnt much from him.

Surgery was now equipped for its great adventure. The science of pathological anatomy had established upon the only sure foundation our knowledge concerning the morbid processes responsible for the symptoms of which a patient made complaint and for the signs which were disclosed when an examination was made. Treatment could therefore deal with structural changes which had been carefully studied. Operations were rendered painless by anaesthesia, and safe by the application of the antiseptic method. The advance that surgery has made in its relief of human suffering, and the prolongation of human life, is incomparable. Nothing that has happened in the world since the birth of time has meant so much in matters of human happiness and welfare. What is the part that Leeds has played in all this great revolution? At the time when Lister was introducing his methods Mr. Wheelhouse (1826-1908) and Mr. Teale (1832-1923) were surgeons from 1864 to 1884. Both contributed new thoughts and new methods to surgery. None of us who knew Mr. Wheelhouse are ever likely to forget him. He was the most punctual man alive. Arriving at the Infirmary less than one minute before eight in the morning, he raised his hand to arrest the porter hastening to sound his bell, and admonished him to wait for the town-hall clock. His bell and the hour struck together. His demeanour was of the most solid gravity; his speech slow and of a solemnity that made one listen with awe to the emphatic announcement of the time of day or the state of the weather. I heard him speak also at medical meetings. What he said seemed, as one afterwards recalled it, to contain no message of any value, but one almost held one's breath as one listened to its massive and deliberate utterance. I saw him operate on a few occasions only; he moved, as he spoke, with the utmost deliberation and emphasis. On one occasion I helped him in a very minor biblical operation. I gave the baby chloroform and assisted at the same time. The operation was done in the ward, and as he walked away with the same brooding sense of the vast and profound significance of every act, I listened to a minutely detailed account of the difficulties that had been encountered in this very operation; of cases in which the operation, full of hazards, had

been abandoned by no less a man than Tom Nunneley; and of the deaths that had followed upon delayed hæmorrhage. By the time we stood upon the doorstep I was the victim of a profound nervous exhaustion, and I felt that the least I could do, in view of the threatening dangers ahead of me, was then and there most solemnly to vow that never would I suffer my own slender skill and my unripe experience to embark upon so menacing an operation as that which I had just witnessed.

Once as I walked past the theatre door with him he asked who was operating. I said "Mr. Teale; and the operation a lithotomy." He stopped at once, and with a gentle push upon my arm he bade me enter the theatre and watch "the most beautiful little hands in England" at work. The description was not, I think, inaccurate. Wheelhouse's originality was shown in his suggestion of a new method for dealing with stricture of the urethra. "Wheelhouse's operation" is known to this day, and if not practised with such frequency as formerly it is because the conditions requiring it are prevented by more careful treatment of the disease in its earliest stages. Mr. Teale and Sir Clifford Allbutt formed the first alliance known to me in this country. They were the pioneers of "team work." Sir Clifford, the most deeply learned physician of this day, master of a style of English which for sheer beauty and majesty is perhaps unmatched by that of any scientific author of our generation; an orator whose speech makes Time seem hasty; a cultured, upright, English gentleman, is the pride of the school he served so long and loves so well. Mr. Teale was the authentic product of Winchester and Oxford, and I know nothing better than that. He was the flawless example of intellectual and moral integrity. He was modest, cautious, reserved; free from any jealousies, ready with words of encouragement, and an occasional word of praise. He had not a creative mind, and we owe no large conceptions to him. His advances were slow but well assured, and he had never to turn back. He gave the utmost devotion to any subject which engaged his eager attention, and though conclusions were slow in finding expression, they became articles of steadfast faith with him. He preached a very noble gospel. The estimate which Mr. Wheelhouse made of his technical skill was not over-generous. He had the faintest hands, the gentlest touch, the most sensitive movements. He was the first to deal with "serofulous glands." When in London he was a pupil of Sir William Bowman. Up to the end of his active life in surgery he operated upon ophthalmic cases, and he devised a new method for the extraction of cataract.

He was a pioneer in domestic sanitation, and his book on *Dangers to Health* became a classic. For his work on hygiene he was made F.R.S. I learnt much from Mr. Teale, for whom I had a deep affection. He was a most comely, truthful, upright gentleman—a man who honours his calling, and whose noble example is not soon forgotten.

Mr. Jessop (1837-1903) was beyond question the most popular practitioner in Yorkshire for a quarter of a century. His experience was gigantic, in medicine no less than in surgery. He was in general practice during the whole of his period of office as surgeon to the Leeds General Infirmary (1870-90), and his consulting practice was almost as large on the medical as on the surgical side. He was the greatest man I have ever known in our profession, for to his massive qualities of intellect he added a grandeur of character unsurpassed. Though I knew him as well as any man, I never heard a heartless word or an ungenerous estimate pass his lips. But his silence could be full of awe; and when need arose he could denounce with devastating emphasis the acts or the qualities he believed to be evil. In his examination of a case he left nothing undetermined; he was methodical, comprehensive, and deliberate. That completed, he would discuss the diagnosis, or the treatment, with the utmost circumspection; nothing in the history or in the signs had escaped him; there was never a need to look again or to feel again. Every detail was remembered and its value measured. All men considered his judgement as the final one, and popular sentiment was not alone in feeling that if Mr. Jessop had not seen a case there still remained something to be done, and

a gleam of hope was still to be found even in the gloomiest outlook. He was indisputably the best, and the safest, operator on the staff. He had developed a technique which for those days was good. His hands were strong, gentle, yet compelling. He was imperturbable. No crisis—and there were such events in his time—ever disturbed his perfect tranquillity of speech or action. He never knew the name of any assistant or house-surgeon, and addressed everyone as "Mister." This became in time his own title, and as "Mister" he was known to many generations of students and residents, who regarded him with the deepest admiration and respect, and with, perhaps, a shade of fear. He, too, was a pioneer. He recorded the first case of successful extirpation of a growth in the kidney in this country, and the first case in which an operation upon a patient with advanced extrauterine gestation saved both mother and child. He was vice-president of the Royal College of Surgeons in 1901.

The greater number of the Leeds surgeons have been home-grown products, trained at the Leeds Infirmary; a few have been imported. The greatest of the foreigners was A. F. McGill, a nephew and godson of Sir William Fergusson. He had the widest vision and the clearest intellect of any member of the staff, and his dexterity, on his best days, was unsurpassed. He had his bad days, too, and it did not take long to discover that these were warnings that the diabetes, from which, with other members of his family, he had long suffered, was beginning to murmur the most ominous threats. He will, of course, be forever remembered as the pioneer in prostatectomy. His first operation was performed in March, 1887. At that time I was his dresser, and by a happy chance was acting as his house-surgeon. A patient with a tumour in the bladder came to his wards, and an operation revealed a projecting mass near the internal meatus of the urethra, which was removed. In those days the house-surgeon cut all sections for his chief. When I examined this tumour I found it was prostatic, and, with a little gloom at the chance to score off my dear master, I met him in the entrance hall the next morning. He asked after the patient, and I said he was doing well, and that the "tumour" he had removed was a part of the prostate. "Oh, was it," said McGill at once, "then why don't we always take the prostate out?" At the British Medical Association meeting in Leeds in 1889 he showed a number of patients, old men seated in a row, each holding his prostate in the jar which still contains it to-day. The question of priority in the performance of prostatectomy has raged fiercely, but no serious controversy is possible. McGill's specimens are as he left them, and they show that from nibbling operations be passed to enucleations, until, at the last, the whole prostate, with a part of the prostatic urethra, was removed exactly as it is done to-day. McGill was a pioneer, too, in gall-bladder surgery, but a most untimely and deeply lamented death prevented his marching with Mayo-Robson along this road which has led to such new and fertile fields.

The surgeon who came at the most pregnant moment and made the fullest use of his opportunities was Mayo-Robson. From McGill, whose dresser I was, and from Mayo-Robson, whose house-surgeon I became in October, 1887, I learned the rudiments of all I have ever known of surgery. Mayo-Robson had been a great prize-winner at the medical school, and he regarded me, I think, with favour from the first because in this direction I had shown a greed hardly inferior to his own. He was never a resident officer, and on joining the staff, he has since told me, he was "very raw." But he had an unquenchable zeal for work, a most acquisitive and retentive mind, and a skill of hand and of eye that made him then a marksman of almost the very first rank and a fisherman of the greatest repute. Coming into surgery at the birth of a new time, Mayo-Robson used the methods of Lister to explore regions of disease which had never yet suffered deliberate assault during the life of a patient. He carried a stage further the work of Spencer Wells and of Lawson Tait on pelvic diseases, and, becoming daily more practised in his art, began to explore the upper regions of the abdomen also. After Lawson Tait had inaugurated the surgery of the gall bladder, the greatest advances made in

our knowledge of cholelithiasis and of its treatment were his. His work on diseases of the stomach surpassed that of any other man of his time. He added greatly to our knowledge of diseases of the pancreas. I thought then, and I am certain now, that in his day there was no surgeon in the world safer than he. His mind was original; he was quick-witted to an amazing degree, seeing in new discoveries an immediate application to some problem or another in surgery; he was as dexterous, as gentle, as accurate in every movement as any man I ever saw; he had an earnest and unwearied desire to help his patients to the utmost of his powers. Perhaps he was not altogether free from the faults of the pioneer and enthusiast. He was a little inclined to make little of his mistakes, or to think that another's share in the work had perhaps been a shade less conscientious than his own. The generous word of encouragement, the word we are all of us the better for hearing on due occasion, did not often pass his lips. During the war he gave noble service to his country: his industry, his devotion, and his great surgical experience were most bountifully given to our troops. The high reputation the Leeds School of Medicine already enjoyed was beyond question greatly advanced by the writings and the work of Mayo-Robson.

Of Edward Ward, an artist among surgeons, and an inspiring teacher, I have so recently written that I need add nothing to-day. He devised an operation for the excision of the larynx, which he practised with a degree of technical skill, and an exquisite perfection of design, that were unsurpassed; and his name is still attached to the single stitch by which the operation of colotomy may be completed.

War is a great testing time, of nations as of men. The tale of the doings of the men of Leeds during the world war has been fully told by W. H. Scott. All the members of our staff, of course, gave loyal and continuous service. Harry Littlewood (1861-1921), as administrator of our 2nd Northern General Hospital, proved himself as competent in the direction of the manifold affairs of that office as he had been skilful and sagacious as a surgeon. Of him, too, I recently wrote in the *Yorkshire Post* at the time of his death, which, as all of us realize, was in no small degree hastened by the intensity of his unremitting devotion to duty during the busy days of war.

As we look back, then, upon the first century and a half of the work of our forebears in Leeds we may in all modesty claim that their achievements are not inferior to those of the staff of any hospital in this country. In range of vision, in the subtle invention of new methods, in the skilful moulding of new practice, they have played a worthy and, at times, a very distinguished part. It has not been our fortune to own a Lister, a Hunter, or a Victor Horsley; the highest pinnacles of all have as yet been denied to us. But among those who cluster round the greatest heights the figures of more than one of our surgeons may be clearly discerned. We of the present time have come into a great inheritance which is not ours to squander or to dissipate. Earnestly must we strive to add something—something of our own, however humble. Perilous as it may be to say so, I believe that the paths which we now follow have been explored nearly to the end. The methods of surgery can scarcely be made more safe than they are to-day. Operations of the utmost severity are performed by the great masters with an absence of risk that leaves little hope of betterment. The chief risk in surgery to-day comes from delay. But though as a measure of therapy the surgical art has now approached perfection, as the handmaid of medicine, as an instrument of scientific research it has still very much to do. Immense though its achievements in this respect have been, we need in these days a broader method. Experimental research, in spite of its occasional fallacies, must march along with us, and the mass of evidence afforded by our surgical work must undergo a wider and closer scrutiny. Clinical and experimental research we needs must have, both extensive and intensive. These are functions of a university, and to our own university we have but now made our plea. When our centenary is celebrated I pray that the speaker who will then take this place of mine may be able truthfully to claim that, great as were the achievements in the early days of our School of Medicine, they have been far surpassed by the labours of our successors.

## Nova et Vetera.

JOHN FREIND.

No English physician is securer of immortality than John Freind, and yet to those critics who, like the old Science and Art Department, pay by results, his claims to remembrance may seem very modest. Munk did, indeed, quote an "authority" who proclaimed Freind's *Emmenologia* to be "admirable for the beauty of its style, the elegant disposition of its parts, its wonderful succinctness and perspicuity, and for the happy concurrence of learning and penetration visible through the whole." But it is not probable that a modern reader will be greatly impressed by the acumen which finds a sufficient explanation of the menopause in the increasing rigidity of the fibres of the uterus and the cicatricial occlusion of the capillaries, "as occurs in piles which have been frequently incised," and explains everything by plethora. The *History of Physick* is metal more attractive. This was a favourite of Sir Norman Moore, and we have heard him say that, while it was enough to have a single edition of most books, he was glad to have a copy of every edition of Freind's *History*. Diligent Germans long ago superseded it as a source of exact information, but nobody is likely to supersede it as a source of pleasure. When one has read this book and looked at Freind's handsome face among the portraits in Pall Mall East, it is not hard to understand why he was loved in the flesh and has left a fragrant memory.

No English have never had any special reverence for very learned or very scientific men; specialists, possessed of and by their subjects, are apt to be accounted bores and pedants. But an enjoying English gentleman—in Bagehot's phrase—who carried his learning lightly, who, by success in practice, proved that he could do something besides write elegant Latin, and who always "played the game," has very rarely failed to command both affection and respect.

Freind had all these qualities, of the high spiritual faculties, creative imagination, and

enduring patience which go to make a Harvey or a Darwin, was wholly destitute. What he had in perfection was a sort of luminous common sense; the physiology of *Emmenologia* is nothing, the description of cases and how he handled them everything. In his commentaries on the *Epidemics* of Hippocrates there is no breadth of vision; he is not curious about the general theory of epidemics, but he is perfectly alive to the danger of getting oneself into a fog. Sydenham, in a very famous passage, said:

"This, at least, on the strength of a multiplicity of accurate observations, I am convinced of; viz., that diseases of the character alluded to, and more especially continued fevers, differ from one another like north and south, and that the remedy which would cure a patient at the beginning of a year, will kill him perhaps at the close."

A striking observation this, and Freind had as much respect as any man for Sydenham; but the question for him was: Did Sydenham in fact produce any evidence for his statement which would pass the common-sense test of practice?

"If we study," says Freind, "the method of treatment which this author has adopted in curing these fevers belonging, as he

says, to utterly different genera, a method in which he was conspicuously successful, we do not find the smallest indication of this diversity."

A man on this level is not perhaps going to make any great discovery, but certainly he will not come upon any gigantic mare's nest.

Freind is, in fact, a true disciple of Horace, keeping to the *via media* of common sense. A wide literary culture saves him from the crudities of the practical man who wishes to see something "on a plate," and even if his eyes are blind to the highest generalizations, he is perhaps a safer model for most of us than more philosophical men. In his *History* these qualities are conspicuous. He was not trying to produce a mere chronicle, but to discover what all the ancient writers were at, what advances they made from the point of view of practice. More learned writers (not that Freind's learning was to be despised) have not always been guided by so good a principle. An edition of

this book which earned for its author Haeser's not lightly bestowed commendation, "one of the most famous writers on the history of medicine," would be a fitting celebration of the second centenary of Freind's death, which will be in 1928.

It is inevitable that the Freind type should grow scarcer in our profession. We shall never, indeed, lack great gentlemen, but wide culture in the humaner letters is no longer universally looked for; familiarity with the "literature" of ductless glands will earn more respect for the young physician than ability to read Quintilian while strap-lugging in the tube. Even the College of Physicians declines any longer to impose upon its members a test of classical erudition. This is, no doubt, inevitable. But we may still have a warm corner in our hearts for the Tory medical M.P. who began his *History* while a close prisoner in the Tower, and lived the life of a scholar and gentleman.

Indeed, it is likely to be one of the most serious difficulties of medical education in the future to conserve the type of which Freind was a fine example. The case for the eighteenth century system of liberal education was that all received a general culture which, however faulty, was

wider than technical education; nowadays the demands of the technicians are so numerous that hardly any time is left for general culture. Mr. Flexner, whose opinion is, of course, entitled to the most reverent attention, has urged us to make our system still more technical, and the days of the Freinds and Lathams are numbered.

"So in entering this place, even this vast hospital, where there is many a significant, many a wonderful thing, you shall take me along with you, and I will be your guide. But it is by your own eyes, and your own minds, and (may I add) by your own hearts, that you must observe, and learn, and profit. I can only point to the objects, and have little more to say than 'see here, and see there.'"

This is an obsolete exhortation if the student is to regard the patients as cases upon whom half a dozen heads of clinical services have furnished expert reports; his time will hardly be long enough to enable him to co-ordinate the findings of the radiologist, the chemical pathologist, the applied physiologist, the ophthalmologist, and the half-dozen other specialists whose observations are placed before him in the most up-to-date of foreign clinics. Let

JOHANNES FREIND, M.D.  
Serenissime Regine CAROLINÆ Archiatrus  
*Qui suas Artes sua dona, laus  
Et Lyram, et Terga Salutaris Totum  
Seire concepit, celerem et Medendi  
Delusit Num.*

him study the report of the cardiologist and not bother about the promptings of his own "heart."

Another remark of Latham is not obsolete; it is this:

"But, in our day, there is little fear that students will be spoiled by the recommendation of their instructors to be content with a scanty knowledge, and trust to their sagacity for the rest. They are not likely to suffer harm by having Sydenham held up as an example for imitation: the fear is of another kind (and it is an a. . . that many men of the best abilities are deterred from prosecuting physics as of the necessity indiscriminately laid upon all for impossible attainments, of which no example is or can be held forth for their imitation."

## THE RURAL PRACTITIONER AND MATERNITY.

BY

MAURICE MOTTRAM, M.R.C.S., L.R.C.P.

In a leading article in the *BRITISH MEDICAL JOURNAL* of November 15th, 1924, surprise was expressed that no general practitioner had taken up the cudgels in the recent conference and correspondence on puerperal sepsis. Doubtless many felt that much might be said, but perhaps thought that we were inclined to be too touchy, and that the remarks made did not bear the meaning that they seemed to do. The leading article, however, seems to confirm the impression that a very definite attack has been made on the general practitioner.

Why were these remarks allowed to pass in silence? Two reasons, at any rate, can be offered. In the first place, it is quite useless to argue when the other side is ignorant. No one would question the right of the various speakers to speak with authority on all matters gynaecological, but I think it is no exaggeration to say that most of them showed a regrettable ignorance of the conditions under which midwifery is practised by a large proportion of the profession. Until they have at least a working knowledge of the various types of practice the advice they give us must of necessity be robbed of much of its value.

There is another possible reason for our silence. Just as the eels in the story got used to being skinned, so we have become used to being criticized. Each Annual Meeting brings its crop of criticism of the general practitioner—some of it just and fair, some pitying and patronizing, and some unfair and in very bad taste. Unfortunately the last is generally copied into the lay press, and the prestige of the profession is lowered accordingly. Such articles as "How to conduct a confinement in a private house" are common, and seem to be written by those who never do it, or, at any rate, not in the country. For example, one enthusiast waits the matter treated as a major operation—the pictures down and the carpet up, the surplus furniture removed. Where to? Presumably into the street, for the husband and rest of the family are sleeping in the only other room, which is already overfull. Another writer seems to depend on a gas stove for his routine. The nearest gas stove is eight miles away. And so on *ad infinitum*. After reading a few lines of these gentlemen's advice one is driven to the conclusion that, however perfect their technique may be, it is useless to the rural practitioner.

This brings me to the root of the matter—the total lack of understanding of the work and conditions of the rural practitioner. To make the matter quite clear I will define the type of man and practice that may fairly be looked upon as rural. He works single-handed in a radius of five miles, he lives eight miles from his nearest town and hospital and five miles from his nearest medical neighbour, he dispenses all his own medicines, he would probably have from 750 to 1,000 insured persons on his list. There are, of course, the mountainous practices, where the conditions are accentuated, and the semi-rural, where they are better. I venture to say that a man running such a practice is generally a good type, and to-day he is threatened with extinction—in fact, the process is well started. I hope to show the relation such a man has to maternity work in the country, and to raise the question whether the maternal welfare will be best served by scrapping him and replacing him with something else, or by trying to improve the conditions under which he works, and so making him a still better type.

In the recent discussion the word "practitioner" was used. It is a bad word, for the work of a rural and urban practice is so different that the question of maternity work in either must be discussed separately. I have had twenty years' experience of rural conditions, and my suggestions apply *solely* to rural practices. I have no advice to offer in connexion with

town practices, of which I know nothing. I would that those who know nothing of the country would be equally reticent.

Most of the points raised by the various speakers and writers are, I think, covered by the following headings, and I propose to discuss them in so far as they have a bearing on the rural practitioner and his work.

### Maternal Mortality.

This, we are told, does not fall, and apparently it is the fault of the person attending the confinement. I find no suggestion as to where the incidence is most common, town or country. We are constantly told that child-bearing is a natural process. But is it? The production of young by the female is natural, but to say that child-bearing by a woman of to-day, with her curved pelvis and various diseases to complicate matters, is a normal process is untrue. In view of the splendid opportunities for trouble to arise it is surprising that things are not worse, though that, of course, should not deter us from trying to make them better. If our knowledge has increased tenfold, the difficulties to be overcome have increased a hundredfold.

### Puerperal Sepsis.

I do not intend to try to define this, but there seemed to be very little agreement at the conference on the subject. All varieties of treatment seem to have their advocates. Suffice it to say that any case that runs a temperature after confinement is a source of worry to the conscientious practitioner, and has to be dealt with. It seems that the person attending is apparently to blame. Dr. Stevenson blames the doctor and absolves the midwife. This is a very serious charge, and appears to be based solely on his interpretation of certain figures. But which, in point of fact, are the cases which run a temperature in the country? Ask any experienced rural practitioner, and he will probably say that it is not the difficult forceps case, which has had no end of handling (with intervals while the operator has to stop to give more anaesthetic), which shows a rise of temperature, but more often the case that has, perhaps, never been examined during labour. In a case of this sort the chances of the doctor being directly responsible are greatly reduced. The fact that just outside the window pigs are wandering about knee-deep in silt may have something to do with the matter, and this is a job for the Ministry of Health.

### Notification of Sepsis.

I am relieved to find that some speakers seem to be losing their faith in this fetish. To some minds a notification to an official is all that is needed to cure every ill. It may be some use to notify an infectious disease in a town; I believe it is. But, speaking of the district in which I live, I have no hesitation in saying that up to a year ago it was useless. There being no hospital to which a case could be removed, the medical officer of health was powerless. It is true that in present circumstances it is possible to get a case into the town infectious hospital *sometime*. But I remember notifying a case of diphtheria in a two-roomed cottage with five inmates. Medical officer of health, district nurses, health visitors—all were useless. When the child was moribund I felt that it might be justifiable to try my hand at a tracheotomy. A neighbour was found who "durst" hold a candle for me. The child revived and lived two days, succumbing when the membrane spread below the tube. He was nursed by his father, who had once looked after a tubed horse. And yet, with this case in my mind, I am asked to enthuse over the advantages of notifying puerperal sepsis! A tin of disinfectant from the sanitary inspector, and a visit in due course from the medical officer of health, who lives thirty miles away, is all that can be expected here.

Professor McIlroy suggests that notification is apt to get the doctor into trouble. In this instance I agree with her. The notification that something is wrong, and the coming of an official who may or may not be tactful, is quite enough to set the husband thinking that the doctor is to blame. What more natural, in the present state of affairs, than that he should bring an action? Recent cases have shown that the fact that the doctor is, from the medical point of view, not to blame has very little bearing on the matter. The judge will make his usual platitudes and the jury find against the doctor.

I would suggest that before we are asked to make further notifications those responsible should set their house in order, and see to it that there is a chance that the notification will bear some useful result. As I said before, I am concerned with the country districts only.

### Specialists.

Regret was expressed recently that a midwife had done her duty in calling in a registered practitioner, the suggestion

apparently being that she should send for a specialist or, though it seems incredible, the medical officer of health himself. The fatuousness of such a suggestion can only be appreciated by those who live in the country. In this district the medical officer of health lives nearly thirty miles away and the nearest specialist gynaecologist forty. Dr. Fitzgibbon appreciates the difficulty, and estimates that over 700 specialists would be wanted. I admit I have not worked it out, but should think that this number might go some way towards supplying the larger towns. To give a really efficient service in the country areas I suggest that nearer 7,000 specialists would be wanted. It would, of course, be possible to appoint a certain number of men as "specialists." Sillier things have obtained official sanction before now. But I fail to see that the parturient woman will be one iota better off, and it will have appalling results in other directions. If there is one man fitted to deal with an emergency (other than the obstetrician, the genuine ones), surely it is the rural practitioner. A bad case in a cottage a mile off the road, two candles for light, a limited supply of hot water and utensils, an ignorant woman to assist, and no medical help nearer than five miles. And yet these cases live and do well. Could our critics do better in such circumstances, or as well?

#### Hospitals.

It has been suggested that all abnormal cases should be sent to hospital. No one is such a fool as to want to tackle eclampsia or a placenta praevia in a cottage. But, as a rule, by the time the doctor sees the case the time for removal is gone.

#### Midwives.

Professor McIlroy refers to these as a "highly trained body of specialists." On what does she base this statement? I should describe them in the country as a hard-working class, but to refer to them in bulk as highly trained specialists is absurd. How did they become so? Was their training superior to that of the average doctor? Is their knowledge of anatomy and physiology greater, or are they by nature our intellectual superiors? It is such random statements as this which make the rural practitioner feel that argument is useless. Doubtless Professor McIlroy's experience of midwives is vastly greater than mine, but I have yet to meet a single one of these highly trained specialists. On the other hand, I have met several who have been positively dangerous. She suggests, further, that the midwives are cutting out the doctors, and appears to derive some satisfaction from this. But is it a matter for congratulation? As a matter of fact it is true, but it is not due to the superiority of the midwives; the reason is largely financial.

#### Finance.

This is a subject that is seldom mentioned, partly because those who speak most at conferences, etc., appear to be enjoying fixed salaries. The last clause in the leading article that I have already referred to is typical: "Provided discussion is carried on from the wide viewpoint of the public good and not from the narrow one of professional interest," etc. Surely the public good is intimately combined with the best interests of the profession. The utter-ignoring of the financial side of the doctor's business, so far from having done good, is going to do the public in the rural areas an incalculable amount of harm. It is an unfortunate fact that practically every innovation which is alleged to be for the public good leads to a diminution of the doctor's income. The worst of us probably rarely spends a day without giving something away, frequently of necessity rather than as a virtue. But it is one thing to give individually among the people that we live with and know, and quite another matter to be called upon to give our services generally and at the demand of public bodies. If we received preferential treatment in the matter of taxation there might be some excuse for it, but no profession is treated more shabbily than ours. All our small privileges have been swept away—for example, reduction on car tax and petrol.

It is absolutely certain that when a district nurse is introduced into a practice the doctor can say good-bye to a slice of his income. The habit arises of calling in the nurse to decide if the doctor is wanted. If he is not wanted the doctor loses the fee he should have had. Often the nurse tries her hand at treatment for a few days. This, when the case is of an infectious nature, may have disastrous results, and I am quite sure that this practising by unqualified practitioners—for it is nothing else—is not for the public good. In the case of the very poor there may be some excuse, but the habit spreads to those who can and should pay fees. The well-to-do farmer's wife has the nurse to attend to the boil on her leg and the child's cut hand. There is an idea that the doctor does not

want to be "bothered" with trivialities. This may be true, and I blame the members of the profession to a certain extent for this idea. Looked at broadly, the doctor has to do a certain amount of work to make a certain income. The simpler the case the greater the profit. The acute abdomen and the difficult confinement are not profitable; the fee is insignificant compared with the amount of work and worry involved.

But it is when we come to the maternity work of the midwives that we find the most crying scandal in the matter of fees. Let us assume fifty confinements per annum in a country practice such as I have in mind. In this district the minimum fee is £2. Among the working classes it is also nearly the maximum, for however bad the case it is no use asking a man for a fee that he cannot possibly pay. The easy cases must pay for the difficult. Of the fifty cases about thirty will be normal—I quote Dr. Fitzgibbon. The doctor gets £60, and it is admittedly fairly easily earned. Let us assume ten cases will be abnormal, and a few of these will be really bad, causing no end of work, and, what is much worse, anxiety. In a poor district it is probable that he will not get more than an average of £3 per case. He has earned every penny of this £30, and it is probable that a little has had to go in anaesthetics and help. The remaining ten cases would probably be better-class cases which would not have the midwife. Thus he gets £90 for forty cases, and, taking the rough with the smooth, it is not too bad. What happens when a nurse is imported? She manages the thirty normal cases without help, and the doctor is £60 out of pocket. And this brings us to the most scandalous part of the business. The nurse, remember, is "cutting the doctor out." Professor McIlroy has said it. She is his professional opponent. She meets with one of the abnormal cases. She is in a difficulty, and this difficulty may have been increased by her failure to diagnose the abnormality early. The general practitioner—for whom, apparently, Professor McIlroy has no use—is sent for. The matter is urgent—the well-being, perhaps the life, of a woman is involved. Human nature prompts the doctor to tell the nurse to get herself out of the difficulty. Ordinary humanity compels him to go, and not only to go, but to abandon whatever else he may be doing. A call of this sort cannot be put off. Now, one would have thought that even a soulless organization like a county council would have had a sufficient sense of honour to pay the man that they are ousting a really good fee when he helps one of their agents in her extremity. A certain speaker (I am not positive of her name, so will not mention it) stated recently that in the circumstances "a fee is paid." She did well not to mention the amount; perhaps a sense of shame stopped her. The fact is as follows. A doctor may be called upon to turn out at any hour of the day or night to help an organization which is admittedly opposed to him, to tackle single-handed any and every sort of obstetrical catastrophe in a patient living at a distance up to two miles from his house (a small mileage fee is paid for longer distances), and to put in all necessary attendance for ten days, and the fee is £2—the same fee that he can get for a normal "B.B.A." Surely, seeing the kid in its mother's milk by comparison a humane and decent proceeding. I feel that I may end my indictment and defence on this note. If those who have read as far look upon this as a fair and just deal, then I have failed indeed.

#### Conclusion.

The matter seems to boil down to this. The maternity service is unsatisfactory, and it is suggested that the general practitioner is to blame. There are three ways in which the matter may be tackled. The general practitioner may be abolished or superseded by a superior service—it is the same thing. He can be left to continue as he is, or his work and general conditions may be improved.

Do those who criticize us really wish to do away with the rural practitioner? Can they offer anything that will take his place?—I mean in actual fact, not in theory. And have they considered what very far-reaching results such a step must have, and whether it will be for the public good, of which we hear so much? I think most of us would be willing to withdraw to fresh fields of activity if a better service can be provided. But can it? The midwives will have to increase vastly in numbers and skill before they can be trusted with all and every confinement. And what of the people of limited means? The *nouveaux riches*, who now inhabit most of the large houses, can easily get their doctor from the nearest town; but there is an enormous majority of people living in the country who cannot afford to pay a doctor to come eight miles to see them, and even if they manage to pay him they are not in a position to get medicines, etc., from a chemist who lives equally far away. I am perfectly sure that if nothing is done to encourage the better class of men to practise in the country, the rural practices, where they still exist, will within twenty

years be in the hands of the very lazy and the very incompetent. I cannot think that this will tend to reduce the maternal death rate in the country.

#### The Cure.

Destructive criticism is useless in itself. I honestly believe there is a means of putting the country practices on a sound footing, a means that will benefit the medical profession—I am quite unashamed of putting ourselves first—the general public in the country, and incidentally in the towns as well. Salvation lies in the erection of numerous cottage hospitals. Every year large numbers of potential good surgeons are turned out from the medical schools. A liking for a country life leads some of these into the country. They get the life they want, but so far as professional advancement goes they might as well have tied the proverbial millstone round their necks. At first they find little scope for surgery. If they undertake it they find that the obstacles to success are innumerable—the best surgeon in the world is useless unless the case can be nursed. Gradually the inclination wears off, and the capacity soon follows. A vicious circle is set up—the less a man attempts the less he feels inclined to attempt, and he gets into the habit of passing his cases on to the nearest hospital; whereas, given the opportunity, he could perfectly well have treated them himself. Now, with a cottage hospital to about every three practices things would be different. Neighbouring practitioners should or would work together,

more partnerships would probably be formed, and team work, with all its advantages, undertaken. As at present, surgeons from larger hospitals would probably be willing to do major operations, but the necessity for such help, now generously given, would diminish with time; there would soon be plenty of capable surgeons in the country districts if opportunity for surgery was offered. The present congestion of the existing hospitals would be relieved. The existing organizations of district nurses and midwives might be incorporated with the hospital nursing staffs, and maternity wards could be arranged for those cases whose houses are utterly unsuitable. Though I love the country, I should strongly advise any young man straight from hospital to give it a wide berth. But with a cottage hospital a country practice would be a very attractive proposition.

There is one bar to this scheme. It will be said that the country cannot afford it. This is untrue. Unlike an individual, a nation can afford anything it wishes for. We had to afford a war, and a very small part of the money spent on this—about three millions a day, I believe—would have gone far to providing a considerable proportion of the necessary hospitals. We can afford vast sums for doles, old age pensions, and education. But the public health makes little appeal to the general public, and as a vote-catching stunt is useless.

Finally, I beg those who criticize the general practitioner as a whole to try to learn something of his conditions, and to consider what the state of the country is likely to be in the future without him or with something worse.

### PULMONARY TUBERCULOSIS TREATED BY SPAHLINGER'S SERUM.

We have been asked to publish the following reports, by two medical observers, of a case of pulmonary tuberculosis treated by Spahlinger's serum at Geneva.

Dr. TH. STEPHANI (Montana) writes:

The following case—Mr. R. G., aged 29, an old patient of mine who has again recently come under my observation—is so remarkable that its details might interest your readers. He arrived at Geneva at the end of July in a most critical condition, with advanced cachexia; an evening temperature ranging between 102° and 104° for eight months previously; pulse 110 to 136; extremely weak; severe coughing—5 to 6 oz. of

FIG. 1.—Radiogram taken May, 1924.

purulent sputum, containing tubercle bacilli in large numbers; cyanosis and distressing dyspnoea necessitating the administration of large doses of oxygen for fifteen minutes hourly; profuse sweating; considerable emaciation; anorexia; prostration; breath foul. Moist râles were present over the whole of the left lung, which was completely involved. There was widely scattered disease in the right lung with a cavity in process of formation at the apex. It appeared as if the end would be only a question of a few days. It was decided that Spahlinger's serum should be given daily in as large quantities as possible. This treatment was started on August 1st, 1924, by injections, by rectum, and by mouth, together with oxygen, digitalin, camphor oil, and eryogenin. The temperature, pulse, and appetite improved rapidly, and the progress of the reduction of the toxæmia was most remarkable. Ten weeks later the disease seemed to be completely arrested. The temperature and pulse were normal; the cough and sputum were almost absent; tubercle bacilli were occasionally present in expectoration, but only in small numbers; he had gained over 1 st. 5 lb. in weight; the lowest weight had not been ascertained. The patient is now allowed to take mild exercise. Chest examination indicates a complete clearing up of the physical signs, the improvement being confirmed by radioscopy.

Of the two radiograms reproduced the first was taken at Meutono in May, 1924. The second, taken recently, shows a striking disappearance of the shadows in the former. Unfortunately the patient's condition was such that no x-ray photograph was possible on his arrival at Geneva.

The large doses of partial serum have rapidly arrested an extensive and severe evolution of the disease where there was practically no hope of a recovery.

I have treated this case in conjunction with Dr. E. Trechsel and Dr. A. Mermod of Geneva, and send you enclosed a report by Dr. B. Hudson of Montana, with whom I saw the patient in consultation.

Dr. BERNARD HUDSON (Montana) writes:

I was asked to see, in consultation, a young man, aged 29, suffering from pulmonary tuberculosis, who was on his way from

FIG. 2.—Radiogram taken September, 1924.

the South of France to Montana. He unfortunately became so ill in Geneva that he was unable to move. I saw him with his doctor on August 1st, 1924, and we were both in agreement that the condition of this patient was well-nigh hopeless. The temperature was running up from 102° to 104° every night, and had been doing so, without intermission, for many months; there were signs of extensive softening in both lungs; he was thin, emaciated, hectic-looking, and coughing up a large amount of offensive purulent sputum. To put it shortly, the patient had all the signs of active and severe pulmonary tuberculosis. Taking into consideration his condition, and the steady downhill course which the disease had been taking during the past year, I considered the case to be quite hopeless, and informed his friends accordingly. The patient himself was very anxious to try the Spahlinger serum; I discouraged this, as I did not think it would have the slightest effect in such a case. However, it was tried, with very beneficial results. I saw the patient again ten weeks later. The signs in the chest had cleared up, the temperature had become normal; he is gaining weight, the sputum is decreasing—in other words, the disease is becoming inactive. I have been asked to report this case, and am pleased to do so, for there can be no doubt that the recovery in this instance is a very striking one.

## Canada.

[FROM OUR CORRESPONDENT.]

### MEDICAL EXTENSION LECTURES.

It is not easy, perhaps, for those in the Old Country to realize the conditions of medical practice in Canada and the difficulties members of the profession encounter in their attempt to keep abreast of the times. Many of the doctors in country districts or even in small villages suffer from an isolation with which, I think, there is nothing comparable in the British Isles. In some of these districts it is extremely hard for the doctor to absent himself, especially from his obstetrical patients, to journey to a large centre and "brush up" by attending lectures and clinics and by watching hospital practice. It is true that there are, for instance in Ontario, county medical societies, and, to attend the meetings, the practitioners, in a very praiseworthy way, travel scores of miles by motor or sleigh, sometimes over roads which are only "roads" in name. Several years ago the Committee on Education of the Ontario Medical Association devised a scheme of post-graduate education for the medical profession. To Dr. J. H. Mullin of Hamilton, a former president of the association, belongs a great deal of the credit for developing this "medical extension" work. The medical faculties of Queen's University, Kingston, of Toronto University, and of Western University, London, have lent great aid by allowing members of their staffs to go out and give lectures. For two successive years the Ontario Division of the Canadian Red Cross Society made a grant of 5,000 dollars to the Ontario Medical Association for this work. On the invitation from a county medical society or from a group of practitioners a lecturer is sent out, and his paper forms the major portion of the programme of the meeting. A booklet of the association gives the titles of the lectures which may be asked for, and these are arranged under eleven heads, such as "internal medicine," "pediatrics," "oto-laryngology," "pathology," "physiology and biochemistry," "radiology," "miscellaneous," etc. There is, for instance, a choice of eighty-four different subjects included in the "internal medicine" list. A series of papers on the same branch of medicine can be arranged. It is not to be supposed that the medical societies rely only on this post-graduate lecture at their meetings; they are encouraged to have papers from their own members as well. The topic of the lecture is first asked for, and only after this has been done is the name of the lecturer sent out. The number of lectures delivered in the year 1921-22 was 241; in 1922-23 it was 249; for the period June 1st to October 31st, 1923, it was 121. The travelling expenses of the lecturer plus an honorarium of 10 dollars are paid by the association. It is satisfactory to note that the scheme has been successful, and that members of the profession are pleased with it. At the San Francisco meeting of the American Medical Association Dr. T. C. Routley, secretary of the Ontario and Canadian Medical Associations, outlined the plan of post-graduate education, and now in the United States a similar one is being adopted, and with, I think, the aid of the Rockefeller Foundation a million dollars has been set aside for the purpose.

### PATHOLOGICAL INSTITUTE OF MCGILL UNIVERSITY.

The new pathological institute of McGill University, which owes its being to the generosity of the alumni of the university, the citizens of Montreal, the Royal Victoria Hospital, and the Rockefeller Foundation, was opened on October 6th (Founder's Day) by the Lieutenant-Governor of the Province of Quebec, the Hon. N. Perceval. There was a distinguished gathering of medical men and representatives of universities in many parts of the world. The Graham Professor of Pathology in the University of London, A. E. Boycott, F.R.S., delivered the chief address of the day. Professor Boycott said that pathology had proved itself able to stand alone as a science, and he welcomed the opportunity afforded at some universities in England and elsewhere to non-medical students, seeking a degree of doctor of science or doctor of philosophy, of

taking pathology as one of their subjects. In his opinion too much time was spent by pathologists in doing routine work, such as the Wassermann test, which should more properly be performed in the clinical laboratories. He made a plea for the study of plant as well as animal pathology, for in both the pathologist studied problems of life. Immediate practical results should not always be taken as criteria of good pathological work, but knowledge of obscure phenomena should be sought for its own sake; in this connexion he cited the work of the young French-Canadian, d'Herelle.

The building stands close to the Royal Victoria Hospital and Medical School, and is connected with the former by an underground passage. It provides more than ample lecture and laboratory room for the present needs of the department of bacteriology, toxicology, and medical pathology. Some of the important features are the large post-mortem amphitheatre, where those of the students not actually helping at the autopsy may watch it being done, a large students' laboratory for microscopical pathology, arranged to secure good window light by placing long tables on a series of wide steps in the floor, and an excellent refrigerating room for keeping vaccines, serums, and cultures. Dr. Horst Oertel, Strathcona Professor of Pathology, is director of the institute.

### THE AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTO-LARYNGOLOGY.

The twenty-ninth annual meeting of the American Academy of Ophthalmology and Oto-Laryngology, with Dr. Walter D. Lancaster of Boston as president, was held in Montreal on September 16th to 18th, when 400 members were present. On the day before the meeting about forty members competed in a golf tournament held at the Royal Montreal Golf Club. The official guest of the academy, Colonel Henry Kirkpatrick, I.M.S.(ret.), of London read a paper on some aspects of primary cataract, and several members took part in a symposium on papilloedema. Other papers dealt with the toxic effects of local anaesthesia, pulmonary complications (with death) after tonsillectomy, and the bronchoscopic treatment of tracheo-bronchial asthma. A short instructional course was given at McGill University for the members. Among the subjects dealt with were the fundamentals and modern treatment of diabetes mellitus, and the part played by the disease in ophthalmology and oto-laryngology.

### VISIT OF THE AMERICAN COLLEGE OF SURGEONS.

A successful meeting of the Mid-West Section of the American College of Surgeons was held in the Fort Garry Hotel, Winnipeg, on September 2nd and 3rd. Operations were performed each morning from 8 till 10 o'clock at the General, Misericordia, and St. Boniface Hospitals. There were many visiting members from the United States. Some of the subjects discussed were the treatment of chronic empyema, gastro-duodenal ulcer, the diagnosis and treatment of diaphragmatic hernia, the differential diagnosis and treatment of non-tuberculous pulmonary suppuration, and the principles governing the treatment of surgical conditions of the large bowel.

## England and Wales.

### THE LEEDS GENERAL INFIRMARY.

Mr. A. L. WHITEHEAD, having completed his period of service on the full staff, is now added to the number of the consulting staff with the right to use six beds. The conditions of appointment of the physicians and surgeons are that they serve on the full staff for twenty years or until they attain the age of 60, when they automatically go upon the consulting staff with the above noted valuable privilege. The term of office as a member of the full staff is, of course, preceded by a varying period on the assistant staff. In the case, however, of those who, like Mr. Whitehead, are attached to special departments, the total period of office is twenty-five years, there being no assistant staff attached to the

special departments. It is only those who have been accustomed to make their regular rounds for many years with a class of students who can understand the wretch which is felt when quite suddenly one day it is grasped that their hospital career is at an end, and we venture to think that the plan adopted at Leeds is worthy of imitation elsewhere. The vacancy created by Mr. Whitehead's promotion has been filled by the appointment as ophthalmic surgeon of Mr. S. D. Lodge, F.R.C.S.

#### REGULATION OF SLAUGHTERHOUSES.

The Minister of Health has made regulations, entitled the Public Health (Meat) Regulations, 1924 (Statutory Rules and Orders, 1924, No. 1432), as to the slaughter of animals for human consumption, the marking of inspected meat, and the conditions of storage, handling, transport, etc., of meat. The Order has been placed on sale by the Stationery Office, price 2d. It is accompanied by a circular to port and other sanitary authorities in England and Wales (No. 547, December 29th, 1924. Price 1d.). The circular has three sections, the first dealing with slaughtering, the second with meat marking, and the third with cleanliness. To admit of the necessary arrangements being made by the local authorities and the trade, the regulations will not come into operation until April 1st next, but applications for the authorization of meat marking will be made in anticipation of the date of the coming into force of the regulations. The Minister has also made an Order (No. 1431), entitled the Rural District Councils (Slaughterhouses) Order, 1924, conferring on all rural district councils the powers of an urban authority in regard to slaughterhouses. This Order also is accompanied by an explanatory circular (No. 552). The price of the Order and that of the accompanying circular is 1d. in each case. Copies of all these documents can be purchased through any bookseller, or directly from H.M. Stationery Office, Adastral House, Kingsway, W.C.2; 28, Abingdon Street, Westminster; York Street, Manchester; and 1, St. Andrew's Crescent, Cardiff. The cost of postage does not seem to be stated.

#### MEDICAL EXAMINATION OF LONDON SCHOOL CHILDREN.

The London County Council proposes to institute, as from April 1st next, a systematic medical examination of elementary school children immediately before they leave school; the purpose of the examination is to advise on questions relating to employment and to co-operate with factory surgeons. Under the present provisions children are medically inspected on entry into school and at about the eighth and twelfth years. It has long been realized that an examination on leaving school would serve a useful purpose, and indeed the arrangements for such examination in certain cases have been in existence for some time past. The routine examination will affect 60,000 children a year, and the additional expenditure will be £5,600 for the first year, and thereafter £6,000 annually. The question will be reconsidered if and when the proposed Factories Bill becomes law and contains provision for the medical examination of young persons employed in factories. The Board of Education has given its approval. The Council is also proposing to make additional provision for remedial exercises.

#### CENTRAL HEATING IN LONDON COUNTY COUNCIL HOUSES.

The Housing Committee of the London County Council has had referred to it the question whether, in view of the recommendations of the Departmental Committee on Smoke and Noxious Vapour Abatement, it would be practicable in the Council's future building schemes to provide smokeless arrangements for warming rooms, supplying hot water, and cooking. The possibility of adopting a system of central heating for the Council's dwellings has been considered, but the cost of providing the necessary installation, in view of the existing restrictions under the London Building Acts on the height of buildings, is held to be prohibitive, as it would involve an addition of between two and three shillings a week to the rents of the tenements. If the present restrictions were removed and it was practicable to provide dwellings of fifteen or sixteen stories high, the question would assume a different aspect. It is thought, however,

that the adoption of a system of hot-water supply for domestic purposes, with or without a radiator in the living room, should be further explored, and in one of the next blocks of dwellings a central heating system is to be installed for this limited purpose as an experiment.

#### CENTRAL MIDWIVES BOARD.

The Central Midwives Board met on December 18th, 1924, when the Chairman, Sir Francis Champneys, presided. Information had been sent to the Board that three cases of the use of nitric acid instead of silver nitrate had occurred on the part of midwives residing at a training institution. The Board considered that the authorities of the institution should be severely censured. Lady Mabelle Egerton was appointed delegate to the Conference of the Royal Sanitary Institute at Edinburgh next July. In reply to a letter from the National Poor Law Officers' Association, the Board decided that no satisfactory intern training can be secured by an institution which does not have at least fifty cases a year. The Board recorded its deep sympathy with the family of the late Dr. J. B. Hellier and its appreciation of the valuable services rendered by him as presiding examiner at the Leeds Centre. A penal session also was held.

## Scotland.

#### JUBILEE OF THE WESTERN INFIRMARY, GLASGOW.

The Western Infirmary, Glasgow, opened its doors for the reception of patients in November, 1875. At the Christmas meeting the chairman of the board of managers, Colonel J. A. Roxburgh, said that during that fifty years many changes had taken place, all in the direction of increasing the accommodation and usefulness of the hospital. In 1875 the number of in-patients was 1,253; last year it was 9,412. There were eight wards in the original building—four medical and four surgical; to-day there were thirty-two wards. The medical and surgical staff when the infirmary was opened numbered 13; now it numbered 61. Even more important was the fact that the efficiency of equipment for the diagnosis and treatment of disease had made steady progress, and numerous departments had been added to utilize all the modern discoveries both in medicine and surgery. The hospital had been established to serve as the clinical school for the University on its then new site at Gilmorehill, and throughout its history had maintained close connexion with the University. At one time four of the professors had beds in its wards; two of the chairs had been transferred to the Royal Infirmary, but the regius professors of medicine and of surgery still conducted their clinical teaching in the Western Infirmary. The small room in which Dr. Coats began the work of the research department in 1875 had been replaced by the splendid buildings of the pathological institute and the clinical laboratory. The Infirmary was one of the earliest hospitals to start an x-ray department, and one of the latest additions had been a massage and electrical department, where patients were treated and women trained for the recognized certificate. Owing to the receipt of numerous legacies, several of them of large amounts, the financial position of the Infirmary was unusually satisfactory. The ordinary income for the year was £67,000, but this left a deficiency of £14,000, about the same as in 1923. The extraordinary income, chiefly from legacies but including £3,350 received from the Voluntary Hospitals Commission, was £94,000. Advantage would be taken of this exceptional state of affairs to proceed with much needed repairs to the structure and equipment of the hospital, at a cost of about £20,000. After providing for the deficiency in the ordinary income it was hoped to carry to capital reserve something like £50,000. The board of managers was anxious to carry out as early as possible the arrangements with the University as to the Gavin P. Tennant chair of ophthalmology, and fulfil its part of the bargain by instituting the department his trustees some years ago had given a sum of money to construct. Unfortunately it was not possible to proceed; the cost of building

had fallen to some extent, but the Rent Restriction Act still precluded the board from getting possession of the intended site. It was hoped as soon as possible to establish a biochemical department, which would involve an expenditure of something like £20,000; towards this about £5,000 had already been received.

#### EDINBURGH ROYAL INFIRMARY RESIGNATION AND APPOINTMENTS.

At a meeting of the board of managers of the Edinburgh Royal Infirmary on December 22nd, 1924, Lord Provost Sir William Sleigh in the chair, the retirement of Mr. Alexander Miles, M.D., F.R.C.S.Ed., from the position of senior surgeon to the Royal Infirmary was announced as taking place, in accordance with the regulations of the institution as to tenure of office, on December 31st. The chairman stated that Mr. Miles had had a continuous connexion with the institution since the year 1889, when he was appointed house-surgeon to Mr. A. G. Miller; ten years later he was appointed assistant surgeon; and twelve years later (January 1st, 1910) he became surgeon. On the motion of Dr. George Mackay, the board minutely its high appreciation of Mr. Miles's service and asked him to allow his name to be added to the roll of consultant surgeons to the institution. Mr. Walter Mercer, M.B., F.R.C.S.Ed., and Mr. William Alexander Cochrane, M.B., F.R.C.S.Ed., were appointed assistant surgeons to the Infirmary out of seven candidates for two vacant posts. It was reported that the receipts for the past two weeks had amounted to over £21,956, which included a donation from the Edinburgh Education Authority in respect of treatment of school children suffering from ringworm, amounting to £300, and a payment of £20,000 on account of a legacy by Mr. James Aitken, Darroch, Falkirk.

#### SANATORIUM ACCOMMODATION IN SOUTH-WEST SCOTLAND.

At a meeting of the Dumfries County Council on December 17th, 1924, Sir William Younger asked for the sympathy of members of the council towards any scheme that might be brought forward to extend the accommodation of the Southern Counties' Sanatorium at Lochmaben. It was opened in March, 1924, with 56 beds, and accommodation is so much sought that there is at present a waiting list of twenty patients. There were 53 deaths from pulmonary tuberculosis in Dumfries-shire in 1923, and, assuming that there were five sufferers from the disease in an advanced form for every death, that meant that in the county 200 to 250 persons were definitely suffering from the disease, with only 22 beds at disposal. In the whole area covered by the Southern Counties' Sanatorium there were 162 notifications of pulmonary tuberculosis in 1923 and 118 deaths. It was therefore impossible to hope for eradication of the scourge unless there were far more than 56 beds available for the whole area.

#### DETECTED METHYLATED SPIRIT.

At a meeting of the Pharmaceutical Society in Scotland on December 17th, 1924, Mr. Anthony McMillan, Glasgow, in the chair, a paper was read by Mr. James Jack, Ph.C., F.L.S., on picric acid and pyridinized methylated spirit. He said that the Board of Customs and Excise, with a view to putting a stop to the habit of methylated spirit drinking, had caused the addition of crude pyridine to methylated spirit to render it undrinkable. This addition had created several difficulties in the use of methylated spirit for pharmaceutical and surgical purposes. For example, a solution of picric acid was frequently used in surgical and hospital practice. Crude pyridine contained several alkaloidal basal substances which formed an insoluble precipitate with picric acid, thus making the new form of methylated spirit incompatible as a solvent. This and other objections to the presence of crude pyridine in methylated spirit had induced the Pharmaceutical Society and the British Medical Association to approach the Commissioners of Customs and Excise with a view to securing elimination of pyridine or permission to use industrial methylated spirit for pharmaceutical purposes.

#### INVERNESS DISTRICT ASYLUM.

From the sixtieth annual report of the Inverness District Asylum by the medical superintendent, Dr. T. C. Mackenzie, it appears that 159 cases were admitted during the year ended May 31st, 1924; this, with 665 persons on the register at May 16th, 1923, made a total number of cases under treatment during the year of 824. The admissions were 14 more than for the previous year but 4 less than the average of the last five years. Of the patients admitted, 51 had previously been under asylum treatment, giving a readmission rate of 32 per cent. The ages of those admitted varied from 15 in the case of one male to 84 in the case of one female; 20 patients aged 70 and upwards were admitted. The patients admitted during the year fell into the following groups: 81 were cases of melancholia; 21 cases of mania; 40 were cases of dementia, of which 11 were secondary to previous attacks of mental disorder from which the patient had not recovered; 24 were associated with senile decay and 5 with epilepsy; 7 cases suffered from congenital mental deficiency, accompanied in 2 by mania and in 1 by melancholia. Dr. Mackenzie found that hereditary predisposition to insanity existed in 55 of the 159 cases, and in 66 of the cases there had been at least one previous attack of mental disorder. In 23 cases these two predisposing causes were combined. Senility was assigned as a cause in 38 cases, and indulgence in alcohol as a factor in 10 male cases. With regard to the discharges, 51 were dismissed recovered, giving a recovery rate on the admissions during the year of 32 per cent. for both sexes. The number of deaths during the year was 73, of whom 21 died from phthisis and 24 from senile decay; these two causes together were responsible for 61.6 per cent. of all the deaths. The report concludes with a review of the attention which is at present being paid to the early treatment of mental disorder, and urges the desirability of establishing a clinic in Inverness for dealing with patients suffering from incipient mental disorder without certification.

#### INDUSTRIAL EDUCATIONAL COUNCIL.

A body known as the Industrial Educational Council has recently been formed in Scotland with the object, among others, of educating the industrial workers on the diseases and sicknesses to which they are liable, with a view to their mitigation and prevention. The programme of the council is a double one: the first is to deal with the origin, history, and development of the various industries, with a view to giving the workers some knowledge of the industries in which they are engaged; and the other part of the programme, which is considered the more important, is a "health programme," designed with the object of educating the workers on the diseases to which they are liable. The council comprises over twenty medical members, the list including a number of medical officers of health for the principal cities in Scotland, and there are over thirty ordinary members and seven representatives of workers. The president of the council is Lord Salvesen and the secretary Mr. J. Mackenzie, who was for several years general secretary of the Y.M.C.A. National Council in Scotland. A special appeal has been issued on behalf of the council by the Lord Provost of Edinburgh, supported by the Lord Provost of Glasgow, and in this it is pointed out that in 1922 it was estimated that no less than 2,100,000 weeks' work was lost through sickness and disablement among the insured workers in Scotland. It is added that a large percentage of this was avoidable. The council is desirous of raising £10,000 to enable the work to be carried on effectively.

#### ST. ANDREWS INSTITUTE FOR CLINICAL RESEARCH.

The spring session of the St. Andrews Institute for Clinical Research will be devoted to the subject of renal efficiency. The meetings will be held on Tuesdays at 4 p.m., beginning on January 13th, when Professor Cathcart, F.R.S. (Glasgow), will read a paper on metabolism, with special reference to the kidney. It will be followed by a discussion, to be opened by Professor Herring and Dr. Hynd. The meetings will continue weekly until March

17th, and it is hoped to arrange a discussion to be held after that date on albuminuria in relation to life insurance. The subjects will be duly announced in the Diary of the JOURNAL. On Thursday, January 22nd, at 4 p.m., Professor Charteris will give a demonstration of kidney cases in his ward in the Royal Infirmary, Dundee. A meeting of the Association for Clinical Investigation will be held in Edinburgh on Saturday, January 31st. The morning session will be held in Professor Murray Lyon's ward in the Royal Infirmary at 11 a.m. An afternoon session will also be held. All practitioners are cordially invited to attend the lectures and discussions. The secretary of the Institute is Dr. J. Hunter P. Paton, St. Andrews, Fife.

## Ireland.

### SIR WILLIAM WHITLA.

SIR WILLIAM WHITLA has been elected a Pro-Chancellor of Queen's University, Belfast. He was educated at Queen's College, and graduated M.D. in 1877 with first class honours and a gold medal. He has been closely associated with Queen's University as professor of materia medica and therapeutics, and when he resigned his professorship four years ago he was elected to represent the University in Parliament. His *Manual of Pharmacy, Materia Medica and Therapeutics*, first published in 1882, reached its eleventh edition last year, and his *Dictionary of Treatment, including Medical and Surgical Therapeutics*, also reached its seventh edition during that year. Sir William Whitla was President of the British Medical Association at the Annual Meeting held in Belfast in 1909. His appointment as Pro-Chancellor will bring great satisfaction to his numerous friends.

### MEDICAL REGISTRATION IN THE FREE STATE.

Mr. P. McGilligan (National University), Minister for Industry and Commerce, referring in the Seanad to the position of medical students who passed and got their qualifications, and who, prior to a date in 1923, were validly registered, said it had been believed that, owing to the joint action of a section of the Constitution and a certain adopting Act, the position prior to the introduction of the Irish Free State had continued. He had attended a conference on the subject, and there seemed no doubt in the minds of the British representatives, but it was deemed advisable that legislation should be introduced in the Free State and in the British Parliament to validate what had been done previously, and continue in operation the General Medical Council for a period to be defined in the Acts. The legislation was to be corresponding, correlative, and complementary. He had introduced a bill as a matter of urgency, and it was almost immediately brought into the Seanad, and while engaged in the Seanad he was informed there was a certain point still in dispute. He had treated the question as one of great urgency, and he asked the House to treat it as such. He had not had any indication of anything seriously affecting the medical profession, and he was not aware of any such situation as had been represented in the press; nothing had happened, so far as he was aware, to change the situation. There had been no indication of any likely action to put an end to the prevailing state of things. The position remained as it was after the conference in London. If those in England connected with the matter did not know the reason for the excitement, if he (the Minister) did not know, and if the people who would be expected to advise him when they thought anything critical was coming on did not know, he (the Minister) did not see that there was any situation developing. At a gathering recently remarks were made by a surgeon which were interpreted in quite a different manner from what was really meant. He had received a telegram to the effect that the position would be unchanged until February, and the interpretation was that if a student were not qualified in January the last chance had gone. The use of the word February was probably due to the fact that the legislation would be passed by February.

At a meeting of the representatives of the medical and dental students of Connaught and Munster the following resolution was unanimously passed:

That the medical students of the University Colleges of Cork and Galway view with strong disapproval separation from the General Medical Council and the establishment of a separate medical council for Ireland, and we, therefore, urge members of the Dail and Senate, and the Irish representatives on the General Medical Council, to take the necessary steps to secure that the present arrangements remain unchanged.

### ROYAL ACADEMY OF MEDICINE IN IRELAND.

At a meeting of the Surgical Section of the Royal Academy of Medicine in Ireland, on December 12th, Mr. A. K. Henry and Dr. D. K. Milne Henry described, with the aid of lantern slides and specimens, an anatomical collection that is being prepared in order to illustrate operative surgery. Each specimen was labelled to indicate the lines of incision, and the various structures were appropriately coloured. Landmarks and planes of cleavage were shown by means of simple diagrams. This collection had been begun at the Royal College of Surgeons, Dublin, with the double object of helping students of operative surgery and of constructing a kind of reference library for the practising surgeon. The preparations shown included the exposure of the popliteal face of the femur from the outer and inner sides; the Sprengel Smith-Peterson exposure of the hip-joint; and Roylo's exposure of the lumbar sympathetic system for section of the rami in spastic paraplegia.

## Correspondence.

### PUERPERAL INFECTION.

SIR,—The question of a prophylactic immunization in preparation for childbirth, raised in the discussion in your columns, is one of great interest and perhaps of some importance, and a brief note of some work on this subject carried out by us in 1913-14 may be of interest.

Working on the out-patient maternity clinic at the London Hospital, under the care of Dr. Russell Andrews and the late Dr. Drummond Maxwell, we inoculated a series of 500 patients with a mixed streptococcus vaccine. The vaccine was made up partly from strains derived from the vaginal cultures of healthy pregnant women and partly from organisms isolated from the blood and uterus of cases of puerperal infection; the latter (mainly *S. pyogenes*) constituted the bulk of the vaccine. Usually two subcutaneous inoculations were made at weekly intervals, and we aimed to give them within two or three weeks of delivery; with an out-patient this date is mostly rather uncertain, but we found that 60 per cent. fell within one month of delivery and approximately 90 per cent. within two months. An amount of the mixed streptococcus vaccine containing 50 or 100 million was given for the first injection, and either 100 or 200 million for the second. Something like 3,500 uninoculated cases which were attended on the charity during the same period served as a control.

During the war years some of the notes were mislaid or lost, but, speaking from memory, certainly one and possibly two of our inoculated cases died of streptococcus infection; this gives a far higher percentage mortality than occurred in the uninoculated part of the clinic, though, of course, with such comparatively small numbers it is useless to argue about it. On the other hand, the general morbidity in our 500, including para- and peri-metritis, was less than among the uninoculated. However, it was clear that we had not achieved our end, and it was our intention to start again, using possibly a sensitized vaccine.

There are clearly serious difficulties in the project, which may be briefly discussed under the following heads:

1. *Infecting Agent*.—In fatal cases almost always a streptococcus, by laboratory classification generally corresponding to the type *S. pyogenes*, is present, but this type may include many strains; quite possibly each strain derived from a human host differs, *ipso facto*, from every other strain. In a certain number of less severe cases a short-chained anaerobic type of streptococcus is found.

These two types of organism would cover most of the severe cases.

**2. Degree of Immunity Required.**—It is probable that a high general degree of immunity would be necessary to prevent an infection with a pathogenic streptococcus gaining access to the uterus. There is, of course, the large raw area of the placental site, but, more than that, the uterus is physiologically decadent and proceeding to involution. In animals a high degree of immunity is only attained by prolonged and rather heroic measures such as are out of the question with the human subject.

**3. Dangers to be Avoided.**—If the danger to the patient is to be nil and the inconvenience slight, as we held it should be, we must rely on a gradual immunization, which is likely to be less effective than that which more active measures would produce. In our series we had one or two swollen arms which distressed the patients rather, but there was no direct evidence that anything in the nature of premature birth resulted from the inoculations, although some 13 per cent. of our series were delivered within the first week after the inoculation. Another danger—that of a temporary lowering of the resistance to infection—is believed to be a possible result of inoculation; our figures do not throw much light on this aspect of the problem.

**4. Finally,** this is an experiment in immunization which must be undertaken in a wholesale way if the figures are to be large enough to eliminate the chance factor, and it is a great question whether our knowledge of streptococcal immunization is sufficiently advanced to warrant this being done.—We are, etc.,

T. H. C. BENIANS.  
S. GORDON LUKER.

London, W.1, Dec. 19th, 1924.

#### THE GENERAL PRACTITIONER AND THE MATERNITY SERVICE.

SIR,—Some of your correspondents are under a misapprehension regarding the object of my letter to the *BRITISH MEDICAL JOURNAL* (October 4th, 1924, p. 642).

My chief purpose was to emphasize the necessity for improved clinical training in obstetrics. The correspondence confirms the opinion originally expressed, that existing educational arrangements are deplorable, and that increased facilities must be provided in the near future, both for undergraduates and practitioners.

As daughter and assistant of a country doctor, having been for some years in consulting practice, I fully realize the splendid midwifery work done by the general practitioner, frequently in face of perplexing and almost overwhelming difficulties, for which in many cases he has not been prepared by adequate training. The thousands of efficient obstetricians amongst general practitioners, for the most part, owe their skill to experience and not to early teaching.

There is another misapprehension. The rest of my suggestions apply only to State-aided cases, and not to private practice. The whole subject demands investigation and reform, and it is hoped that before long a Royal Commission may be appointed.—I am, etc.,

London, W.C.1, Dec. 22nd, 1924.

A. LOUISE McILROY.

SIR,—Writing on the above subject in your issue of December 20th, 1924 (p. 1177), Dr. Alexander Blair has quoted a paragraph from a previous letter of mine, and has gone on to interpret it in a manner so wide of the mark that I am obliged to correct him.

I have not now, nor ever have had, a contempt for general practitioners—I have, on the contrary, many friends and acquaintances among them for whose work I have the greatest admiration, and am not vain enough to suppose my experience in this respect to be unique. I have criticized, on occasion, the actions of individual practitioners or groups of them, and have been subject to the same criticism myself.

Unskilled midwifery means mismanagement of the child-bearing woman at any time from the commencement of pregnancy to the end of the puerperium, and sharing the responsibility for it are medical officers of health and their subordinates engaged in maternity and child welfare work,

hospital consultants, general practitioners, midwives, the women themselves with their fears and resulting prejudices, and their well meaning but sometimes ignorant relatives. We are all in it; and if drawing attention to the matter gives special offence to general practitioners, it would suggest that they are no more easy in their minds about the obstetrical side of their work than are practitioners of preventive medicine—which is a wholesome state of mind and to be encouraged until improvement comes about.

As regards suggested panaceas we are bound to differ according to our respective points of view and work experience; but may I suggest to Dr. Blair that it is a little invidious (even to the accompaniment of a complimentary epithet) to stigmatize the views and faiths of other medical workers as "pathetic," and also that the tide of organization, specialization, and officialdom being fully upon us in this twentieth century A.D., it were well to use it to our patients' advantage rather than try to sweep it back with a Mrs. Partington's broom.—I am, etc.,

Wilkesden, Dec. 23rd, 1924.

AGNES HILL NICOLL.

SIR,—In the interests of the community and of the medical profession I feel, as a practitioner of thirty years' standing, that it is my duty to protest against the tone of perfection advocated by Professor Watson in his address to the Edinburgh Obstetrical Society. Professor Watson's ideal is magnificent but is entirely unsuited to society as it exists. The net result of the elaborate precautions advocated is that the young men immensely magnify their office and charge such enormous fees that the public are ceasing to employ them, greatly to their own detriment and to the destruction of the doctors. My experience, though not great, has been spread all over England. I held every student appointment possible at Guy's, and when "Charity" over five hundred cases were attended. Over three thousand cases per annum were attended by students in the poorest districts in the Borough, and yet the deaths averaged 3 per annum from all causes. If such a result could be attained without the lofty but impracticable methods of Professor Watson, why rob the community and the doctors of their just dues? The bulk of puerperal fever, as Dr. Conyns Berkeley has declared, is due to auto-infection, which I know to be true, as in the cases of sepsis I have had in my own practice the children have had suppurative ophthalmia, which must have been due to maternal vaginal infection.

Those infected by the attendants are, in the opinion of a vast number of doctors, due to dirty hands. What other reason can be effective when one considers the experience of the Guy's charity? The men soaked their hands in mercury perchloride 1 in 1,000, and again they soaked them. The necessity of mercurial antisepsis had been rubbed into them. The primal focus of mischief is unwashed hands. Wearing gloves causes a man to be less careful to wash his hands, and lack of sense of touch renders him less careful to soak them constantly. Professor Watson will say they should not, but they do.

Dr. Peter Horrocks used to tell us that one cannot be sure of an occipito-posterior position. All of us have seen breeches mistaken for heads, or on by the cracks. It is the general experience that a greatly huddled case rarely becomes septic. Clean hands and no vaseline, and there is no need for all the precautions that have robbed the public of their rightful attendants. The ante-natal teaching is admirable, but the fallacies are terribly frequent.—I am, etc.,

East Sheen, Dec. 28th, 1924.

VAUGHAN FENDRED.

#### NEAR SIGHT AND CIVILIZATION.

SIR,—I have read with much interest the account of Sir Arthur Keith's lecture in the *BRITISH MEDICAL JOURNAL* of December 20th, 1924 (p. 1172), in which he alludes to my theory of myopia, and states that if muscular exercise caused myopia all would suffer from it; but the same argument might be used with regard to tuberculosis, in which only a certain proportion of those exposed to infection contract tuberculosis. If the direct exciting cause of myopia be increased intraocular pressure, as I am firmly convinced it is, whether the eye will dilate or not will depend upon

the strength of the eye and the condition of the health of the person. For instance, a boy in a debilitated condition, as after measles, may become myopic on lifting heavy weights when in his normal health he would escape.

The general athlete rarely becomes myopic; probably through training his eyes have acquired a strong power of resistance. Myopia appears to be caused, and may appear, at any age, particularly in those who having had a sedentary occupation suddenly take to one which causes a considerable and intermittent increased intraocular pressure, as for instance a shop assistant who becomes a carter and has to lift heavy weights which would present no difficulty to a stronger man. The forms of exercise to be avoided are those which cause the veins of the neck to stand out, thus obstructing the return of blood from the eyes.

If this intermittent increased intraocular pressure be avoided the eyes may become less myopic or even emmetropic.—I am, etc.,

London, N.W.2, Dec. 20th, 1924.

F. W. EDRIIDGE-GREEN.

#### APOMORPHINE IN ANGINA PECTORIS.

SIR,—I happened to see to-day a letter by Mr. Cyril Helm, D.S.O., F.R.C.S., in the *BRITISH MEDICAL JOURNAL* of June 28th last, on the treatment of angina pectoris, in which he describes a fatal case of an anginal seizure.

Although very late, I should like to draw attention to the effect of a hypodermic injection of apomorphine in such cases. I have seen it act like magic, and I have suggested this treatment to several medical men, who have reported surprisingly good results. The use of this remedy came about in a somewhat curious manner. A bush doctor in Australia (the late Dr. Symes) told me that he was called in one evening to see a man who was suffering from an agonizing pain over his heart. He was pulseless, speechless, and apparently dying. In order to afford some relief he hurriedly gave him a hypodermic injection, as he thought, of morphine, but to his horror he found that by mistake he had given apomorphine. He consoled himself with the thought that, in any case, the man could have lived for only a very short time. To his intense astonishment, in a few minutes the pain stopped, the pulse returned, and the man was able to lie down in comfort.—I am, etc.,

ALEXANDER FRANCIS, M.B.

London, Dec. 26th, 1924.

#### REX v. BATEMAN.

SIR,—From the report of the trial *Rex v. Bateman* it is difficult to gather the grounds upon which Dr. Bateman was convicted for manslaughter. It is clear: (1) the uterus was ruptured, but it is not stated when or how; (2) the uterus was removed with the placenta; (3) the rupture of the uterus and the removal of it did not cause death, either by shock or by bleeding; and (4) death was induced by septic infection—a common enough ending to parturition without any tear of any part of the genital tract. It will be no wonder if the verdict of the court should create consternation amongst practitioners who are engaged in midwifery practice. We may ask, Why any sentence and not acquittal?

A matter of great importance regarding the dispensation of justice has been brought to light in this case. A pathologist, a non-practising doctor, who in all probability has seen but little if any obstetric work, and has never been actually engaged in it, has permitted himself to give in a court of law an opinion which laymen, from the learned judge downwards, would undoubtedly accept as equivalent to that given by a real true expert on the subject. The opinion given was "that if the woman had been operated upon she would have had some chance of surviving, and that she would have been fit for an operation before she was removed to the hospital."

The pathologist can hardly have realized that by so acting he placed himself in a false position, and in that of one who knows. In reality, among his professional brethren, he could not pretend to a practical knowledge or acquaintance with either midwifery or surgery. Moreover, as he had not even seen the patient; obviously it was impossible for him to judge whether the woman had any chance of recovery after an operation or whether she was

in a fit state for removal before the date actually determined upon.

The injustice that might arise from the expressions of opinion by a pathologist in a court of law upon subjects outside the scope of his work concerns all doctors throughout the land; and from the trend of events it would appear that the time is ripe for concerted action by doctors for restating in unmistakable terms their relation to the public, and for the public to realize that their best safeguard lies in the willing acceptance of responsibility by qualified medical men for the treatment of their injuries and diseases. Without that willing acceptance regularized doctoring must inevitably come to be worked on a contract basis between doctor and patient. Medical practice under such conditions would soon get into a deplorable state, and that would mean nothing less than ruin to British medicine.

I apologize for the length of my letter, and my only excuse is the gravity of the situation revealed by this trial.—I am, etc.,

Cambridge, Dec. 22nd, 1924.

JOSEPH GRIFFITHS.

SIR,—Every medical man practising in an industrial area—that is, one where midwives flourish—will read the account of the trial *Rex v. Bateman* with grave uneasiness. The average midwife seldom sends for a doctor until forced by the relatives to do so, and when we are called in to deal with a case of prolonged labour it is generally to find the patient weak and frightened, worn out with pain, and some complication which should have been dealt with hours before. Under these unfavourable conditions we do our best. Most of the cases do well. But it now appears that this is not enough. If our treatment is unsuccessful we are liable to be prosecuted for incompetence, and, if we lose the patient, perhaps to be convicted of manslaughter. It is an intolerable position, for no one who is not actually present at a case can form a just opinion of the difficulties encountered and the skill brought to overcome them. There is no definite evidence that Dr. Bateman was grossly unskilful, and he was working under very bad conditions—how well we can all picture them! When he discovered the truly appalling calamity of a uterus torn out he admittedly did all that was possible for the unfortunate woman. Yet he is guilty of manslaughter. In my opinion the conviction is unjust, and if it is not quashed on appeal I suggest that doctors should in future cease to attend midwives' cases at the patients' own homes, but send them all into hospital. I do not believe the results would be any better, and the patients would certainly object, but we should at least escape the possibility of a fate like Dr. Bateman's. Also we should preserve our self-respect, for I do not see how we can preserve it if we feel that our actions and treatment may afterwards be criticized by ignorant laymen.

We are not told the post-mortem findings in this case, but if the woman was really in labour for forty-eight hours with a transverse presentation, spontaneous rupture and separation of the uterus are possibilities. The absence of an account of the nurse's evidence is to be regretted.—I am, etc.,

Hebburn-on-Tyne, Dec. 20th, 1924.

H. C. BROADHURST.

#### PROBLEMS IN NUTRITION.

SIR,—To those of us who are specially interested in the relation that exists between dietary and stamina, dietary and longevity, and dietary and fertility, your report of Colonel McCarrison's lecture (December 13th, 1924, p. 1126) comes as a record of observations of extreme value.

I well remember investigating the dietary of some Sikh regiments at Lahore. I knew that they were men of splendid physique, tall, stately, agile, capable of great endurance, and renowned for their courage. I asked them if they ate meat, and they said that at home they did not, but that when they joined the army they did. I then inquired how many ounces or pounds each man ate a day. At this there was great hilarity, and then it was explained to me that once a month, on pay day, each company clubbed together and bought one little goat, and this they killed and cooked and ate! A few ounces apiece once a month!

It would be well for every practising physician who has

been brought up to believe in the value of flesh foods and meat broths and beef teas, for the promotion of and restoration to health, to ponder carefully the nutritional problem involved in the statement by Colonel McCarrison, that among races who lived upon a lacto-vegetarian diet "the highest degree of physical efficiency . . . among any of the races of mankind was found," and that peoples in the extreme north of India who lived upon a lacto-vegetarian-fruitarian dietary "had exceptional powers of physical endurance, gastro-intestinal disease was extraordinarily uncommon, and they retained vigour to a very old age." It is well to remember that the climate in this part of India is more trying than in England. I have been almost baked during the day there, and almost frozen during the night.

Now that the importance of dietary in health and in disease is being recognized, it is well to note and record with the greatest care all accurate observations that can be made upon considerable bodies of men and women.—I am, etc.,

Repallo, Italy, Dec. 19th, 1924.

JOSIAH OLDFIELD.

#### MILK AND ARTERIO-SCLEROSIS.

SIR,—As long as the average adult only tolerates the presence of milk in his cup of tea, it is rather a stretch of the imagination to assume that such small quantities as are imbibed can damage the arteries. Now if it can be shown that the incidence of arterio-sclerosis is greater in America and Scandinavia than in this country, I shall sit up and take notice. The type of person whom one comes across suffering from this complaint does not exactly strike one as being a milk maniac—unless it is "Bristol milk"! And if the calcium in cow's milk is indicted why should ordinary hard drinking water be exempt?

It has been stated that the calcium in cow's milk is in a non-ionized form, and that therefore, in order to be utilized by the tissues, it must first be ionized. Certain ductless glands are supposed to be responsible for this work, and what is not required for body needs is passed in the faeces as calcium soaps and otherwise. I do not venture an opinion as to whether the proteins of milk can be regarded as a factor, but I cannot see how calcium can.—I am, etc.,

Wellington, Salop, Dec. 13th, 1924.

A. D. SYMONS, M.D.

#### ACCLIMATIZATION TO HIGH ALTITUDES.

SIR,—May I claim the courtesy of your columns to suggest to Dr. Haldane and other investigators of the physiological problems of high altitudes that the main aspect of the case has escaped attention? A careful examination of the signs and symptoms of disordered function which occurred in the members of the Mount Everest expedition during the ascent, points inevitably to the conclusion that such manifestations are identical with those of the gradual and rapid onset of hyperthyroidism.

The first sign of trouble is tachycardia accompanied by panting on slight exertion, followed by nausea, difficulty of sleeping, giddiness, lividity, loss of muscular power, persistent wasting, diarrhoea, mild tremors, mental confusion, and in a few cases sudden death. All the classical signs and symptoms are exhibited, even to the distaste for meat.

McCarrison, in his classical book on the thyroid gland, states that the thyroids "in healthy animals, living at sea level, or 1,000 feet above, are in the colloid or resting stage." He adds that "the functional activity of the [thyroid] gland appears to increase with residence at increasing heights above sea level." This, I submit, is the true explanation of the clinical syndrome observed in the historic ascent of Mount Everest.

Dr. Haldane notes in his lecture (BRITISH MEDICAL JOURNAL, November 15th, 1924, p. 885) that cases showing neurasthenia or disturbed action of the heart developed most urgent symptoms when submitted to a slight diminution of atmospheric pressure. This is a most interesting and suggestive note. Many cases labelled neurasthenia and disordered action of the heart are in reality suffering from overaction of the thyroid gland. If diminished atmospheric pressure causes increased urgency of symptoms

of thyroid overaction, it is but natural to suppose that increased atmospheric pressure would diminish the urgency of these symptoms, and it is possible to imagine that, in the future, treatment of hyperthyroidism may proceed along these lines.

It is found that Italians stand increased atmospheric pressure well and are therefore generally made use of for caisson work. It is significant that the quick, brilliant, emotional Italian with flashing eyes suggests an active thyroid and a high basal metabolic rate, and his use for caisson work appears to support the theory that an over-active thyroid would benefit by increased atmospheric pressure. The phenomena of "caisson disease," or compressed air illness, may be explained as due to exhaustion of the thyroid gland and subsequent hypothyroidism. The "heuds" complained of by caisson workers are similar in origin to the contractions of tetany following complete extirpation of the thyroid gland. It is to be expected that men showing signs of slight hypothyroidism and a low basal metabolic rate, as evidenced by a somewhat stolid countenance, slow pulse, and slow speech, would, other things being equal, make the best air pilots and members of any future Mount Everest expedition.

Medical experience of the examination of airmen comes into line with this theory. Many of the essential tests of air efficiency are based directly or indirectly on a stable thyroid gland. It is well known that after a great shock an air pilot becomes nervous and loses efficiency in the air. Maublane and Ratié in their manual of examination of airmen note that a number of pilots showed marked acceleration of the pulse at starting, which was even more marked on landing. This is a most important matter for the safety of the air service, and it is possible that eventually the test of efficiency for pilots during service will be based on the estimation of the basal metabolic rate, or some better method of estimating the activity and stability of the thyroid gland.

It is tragic to think that if the cylinders of oxygen carried by the Mount Everest expedition had been left behind and some tablets of quinine hydrobromide, pancreatin, insulin, bromides, and possibly parathroid, had been taken instead, the expedition might have had a successful issue and valuable lives have been saved.—I am, etc.,

London, W.B. Dec. 14th, 1924. A. M. GALE, B.Sc., M.D., Glas.

#### CRITERIA OF TRANSMISSION AND CULTIVATION OF ENCEPHALITIS AND ALLIED VIRUSES.

SIR,—Dr. McCartney, in the BRITISH MEDICAL JOURNAL of December 20th, 1924 (p. 1159), makes several sweeping assertions concerning the results of experimental investigations into the etiology of encephalitis lethargica. For my purpose it will be sufficient to quote part of his summary, where he states that "normal stock rabbits reveal in a high percentage of cases lesions identical with those described by other workers as evidence of the experimental transmission of encephalitis lethargica." Now, being one of those other workers specifically mentioned, I cannot allow this statement to pass unchallenged. Here I shall be as brief as possible, as my opinion on this criticism, which was originated by Dr. Flexner in America, has already been published both in this country and in America. For the following reasons the arguments put forward by Dr. McCartney are invalid:

1. Spontaneous encephalitis of rabbits, whatever its frequency may be in America, is a rare disease of our animals.
2. Only the inoculation of virulent material from human cases of encephalitis lethargica produced an encephalitis in rabbits, and never the control material.
3. Spontaneous encephalitis of rabbits is mainly a chronic disease, whilst experimental encephalitis is an acute infection.
4. The histological lesions of the two diseases are sufficiently distinct to be readily distinguished by microscopical examination, whilst the possibility of the demonstration of the parasite of spontaneous encephalitis gives a conclusive distinction.

In view of the above facts I do not think that Dr. McCartney's criticisms are applicable to the work done in this country, and as far as I know there is only one instance where the disease was transmitted to rabbits from human encephalitis bears any resemblance to the spontaneous encephalitis of rabbits. We admit that there is still much

to be learned concerning the etiology of this protean human disease, but criticism to be helpful must take cognizance of all details.—I am, etc.,

JAMES MCINTOSH.

The Bland-Sutton Institute of Pathology,  
The Middlesex Hospital, London, W.1,  
Dec. 22nd, 1924.

#### CYCLE DELIVERY OF GOODS AND HEART STRAIN.

Sir,—During the past fifteen years I have treated an ever-increasing number of cases of heart strain in boys of 14 to 18 years of age, whose occupation consisted in the delivery of goods by means of cycles with carriers. The heart symptoms were generally progressive, appearing after one or two years' work. They presented more or less the same features—namely, dyspnoea, faintness, or giddiness, with tachycardia, and the apex beat displaced downwards over a somewhat diffused area. The weight carried by these boys ranged from 10 to 80 lb., which, against a strong wind or uphill, represents considerable energy in foot-pounds. There does not appear to be any existing law which fixes the maximum weight to be carried on cycles by boys. Though the work could be efficiently done by dog traction, as seen in Belgium, Switzerland, and Luxembourg, this is forbidden by an Act of 1854.

Therefore, as dog traction, even under the best conditions, is barred, and there does not appear to be any legislation whatever controlling the weights carried, boys in increasing numbers are receiving irreparable heart injury, directly due to the excessive strain caused by their work during a susceptible period of their lives. The majority of the cases I have seen had no rheumatic history or evidence of pre-existing heart trouble.—I am, etc.,

J. H. KEPPEL-COMPTON, M.R.C.S.,

Southampton, Dec. 9th, 1924.

L.R.C.P.

#### TREATMENT OF MOBILE BACKWARD DISPLACEMENT OF THE UTERUS.

Sir,—I was much interested in Professor Donald's paper published in your issue of December 13th, 1924 (p. 1087). In February, 1924, I collected and published (*Lancet*, February 2nd, 1924) a series of 50 cases in which sling operations had been performed for retroversion between the years 1916 and 1922, by various members of the staff of the Hospital for Women, Soho Square. While excluding cases of retroversion in the presence of prolapse, my results are not strictly comparable with Professor Donald's, as cases other than mobile retroversions have been included in my series, but they serve strongly to support his statement that "complications are generally the only things that matter in retroversion and not the displacement itself."

Of the 50 cases operated on in my series no fewer than 31 had complications—most commonly pelvic adhesions and inflamed tubes; and of the 20 per cent. of cases cured and 26 per cent. relieved by the sling operations, 80 per cent. had complications requiring treatment.—I am, etc.,

London, W.1, Dec. 22nd, 1924.

ALICE BLOOMFIELD.

#### "SAUCE FOR GOSLINGS."

Sir,—I am a frightened gosling. I want some old gander (a nice respectable one) to tell me what I may, or may not, do. How can I write when I want to without the risk of being called to stand before the judgement seat? As things are, those of us who use pen and ink and paper in a laudable attempt to illuminate other people's darkness seem to be in considerable danger. At any moment we may be charged with "advertising"; and, if so charged, we shall find it difficult to rebut the charge. A man who writes for the public cannot help getting his name before the public. I have done it many times, and, so far as I know, I have been the only sufferer. Prospective patients shook their heads and sought medical counsel elsewhere. They were misguided, but they were logical. They argued that a doctor who wrote things down on paper could not also find time to listen properly to their tales of woe: they knew nothing of the infinite capacity for work of a general practitioner!

I am in complete agreement with Dr. Harry Roberts when he suggests that it is time for the collective opinion of the

profession to express itself on this question of medical publicity. The outside world is laughing at us—not without reason. We are accused—also not without reason—of being parties to the establishment of a very real and very powerful medical priesthood. We are reminded that in 1215 Pope Innocent III prohibited any operation in which blood was shed; and we are asked how long it will be before some other powerful person issues an edict forbidding any enterprise in which ink is shed! Do we not, as a profession, take ourselves a little too seriously? After all, ours is said to be a liberal profession. Yet in more than one direction it is possible to hear the rattle of fetters. There can be no harm in an examination of those fetters before we adopt them for constant wear.

In this question of medical publicity, I suggest, the one thing that really matters is the manner of the publication. Vulgar publicity must be frowned at. It is all a question of good taste.—I am, etc.,

Walsall, Dec. 21st, 1924.

FRANK G. LAYTON.

#### ANTISEPTIC PASTES.

Sir,—Your leader on "Listerism and War Wounds" (December 27th, 1924, p. 1205), referring to a new chapter, "Postscript, 1924," says it will revive many memories and stimulate thought; it calls to my mind the fact that while the use of "bipp" was undoubtedly instituted by Mr. Rutherford Morison, and generally sanctioned by the weight of his authority, a preparation of the same character, approximately, was employed in France in January, 1915, in No. 11 General Hospital. At that time a sapper officer, well over 6 feet in height, was a patient, suffering from a butterfly fracture of the femur below the trochanter, with gas gangrene; his wounds were so extensive that dressing without an anaesthetic was impracticable, and nitrous oxide gas was administered daily by George Chapman, whom many will remember as a London Hospital rugger forward, and who was killed a few weeks later at Neuve Chapelle. Unfortunately, the supply of gas ran out, and the difficulty of dressing the wound became acute; but a compound of iodoform 1 part, bismuth subnitrate 2 parts, with sufficient glycerine to render it viscous, was suggested by the late Philip Ferguson, F.R.C.S. This was injected into the depths of the wound and smeared over the surface, at first every third day, later once a week. The success of the mixture was immediate, the temperature chart showing a drop to normal and remaining there for the period of the officer's stay in France. Owing to the extreme height of the patient he was treated on a specially made quadrilateral box, covered with canvas, having a compartment for each limb and an area cut out underneath the wound area. He was ultimately transferred to England, and after some early difficulty in persuading the surgeons there to allow him to retain the limb, he made an excellent recovery, and was, I believe, the first "fractured femur" to return to duty in France.

Reference to Sir George Makins would, I think, confirm these statements. It should be noted that the technique differed somewhat from Mr. Rutherford Morison's, in that glycerine, then available in sufficient quantity, was employed as the excipient, and that no attempt was made to close the wound, no "excision" having been effected. At the same time, I have long felt it due to Ferguson's memory that he should have some of the credit of bipp. Our mixture was employed in many severe cases at that time, but with the dispersal of many of our officers to the line I fancy it fell into disuse until the bipp revival in 1916.

At this season one's thoughts hark back to old times and to friends who have gone. Philip Ferguson, who was a Manchester man fresh from doing a job at Golden Square, survived the war, but died early in 1919; S. W. McLellan of Liverpool, who was our bacteriologist and took much interest in our "bismuth porridge" cases from a cultural point of view, also died—on his honeymoon—in 1919. Those who have had the opportunity of reading the private diary of the war kept by the latter will share the opinion of his personal friends as to the loss that literature as well as medicine sustained by his untimely death; he illuminated everything he touched, from bacteriology to bull-dog rearing.

It makes a commentary on the grimness of the long struggle that of twenty-five "Irregular" officers who were a hard-wrought, whole-souled, and happy mess in the early months in No. 11, I can trace no more than four alive at Christmas, 1924.

With apologies for the discursiveness of this letter, I am, etc.,

Sunderland, Dec. 25th, 1924.

W. GRANT WATGH.

#### NOTIFICATION OF INFECTIOUS DISEASES.

SIR,—The Infectious Disease (Notification) Act, 1889, enacts that—

"A medical practitioner attending on or called in to visit the patient must, on becoming aware that the patient is suffering from an infectious disease, forthwith send to the medical officer of health a certificate, stating the name of the patient, the situation of the building, and the infectious disease from which, in the opinion of such practitioner, the patient is suffering."

Does this mean that in the following cases all the medical practitioners concerned shall notify the case and receive the legal fee: principal and assistant or locumtenents, medical practitioners in partnership, transfers from one practitioner to another in the area of the same local authority?

Is there any recognized custom in such cases? A comment in *The Lancet* of England, vol. 23, p. 448, on the above section suggests that where more than one medical practitioner attends a patient the obligation to send a certificate seems imposed on each one, and each is entitled to a fee.—I am, etc.,

Worcester, Dec. 22nd, 1924.

ARTHUR FOSTER.

\*\* Section 3 (b) of the Infectious Disease (Notification) Act, 1889, reads: "Every medical practitioner attending on," etc. On page 821 of the seventh edition of Lunn's *Public Health Acts*, vol. i, there is an annotation to the effect that "in reply to an inquiry addressed to them on the subject the Local Government Board stated that they were advised that if more than one medical practitioner is attending on or called in to visit the patient, each practitioner is bound to send a certificate, and is entitled to the prescribed fee." The recognized custom is, however, for a local authority to require only one certificate. If in any particular instance a practitioner is in doubt as to whether a case has been notified he should forward a certificate to the medical officer of health, and he will be paid the usual fee.

#### ADMINISTRATION OF MEDICAL SERVICES.

SIR,—I suggest that the question of administration of medical service is one that requires consideration. National health insurance has set up an incomplete State medical service, and when that has been extended, and 60 to 70 per cent. of the population are included in it, independent practice will be considerably smaller. Only men in public posts—and not all of them—appreciate the effect of a certain doctrine that doctors are incapable of controlling medical affairs. One explanation given is that they are not business men. It is curious that this is often accepted as a complete explanation, and there is failure to perceive the anomalous position of the doctor. It will be impossible to correct long-standing ideas in a few months, and it might be desirable to consider the subject before any definite proposal for a complete State service is made rather than wait to hear what is proposed.

The root of the matter seems to be an indefinite relationship between the profession of medicine and society. When Governments appoint Royal Commissions to inquire into matters of public health and omit to make doctors their representatives, they nevertheless take care to call medical evidence. It would seem that work is valued, but space for working in is not estimated.

Local government bodies who appoint medical men to advise them in health administration delegate authority to lay officials so that public health may be represented. Therefore, speaking generally, advice is sought and in most cases is followed, but authority and representation are not allowed. Of course, this arrangement pleases those who are put in the intervening positions, and all of them agree that

doctors are unfitted for administration. The latter term, of course, is comprehensive, not limited to certain branches of work, and a duo advantage is taken of its full meaning.

In this way men who write letters, add up figures, and see about repairs, come to control medical service. The effect is not fully realized by the majority of doctors because they have not come into sufficiently close contact, but opportunity will arise when a full-blown State service comes into force governed on these lines. It will be too late to do anything then, however.

To illustrate by comparison: Suppose the general principle now in force to be applied in its literal form elsewhere; suppose it to be held that a professional soldier can only act in an advisory capacity; then an army would be commanded by a layman, representing public authority, who would have under him a general for the purpose of advising him on military actions that had to be taken. One need hardly say that administrative schemes like this do not work well, and actual examples from medical services could be given of their failure and the modifications that necessity has demanded.

What good purpose is served by retaining a theory that breaks down in practice? To begin now to take practical steps to secure proper status and proper measure of control over their services for all men in whole-time posts would commence a new period of progress from which the whole community would benefit. The first and easiest step is at the bottom, where the doctor's case is unanswerable.—I am, etc.,

Southend-on-Sea, Dec. 8th.

R. A. S. SUNDERLAND.

#### Obituary.

R. R. G. RUSSELL, M.D.,

Assistant, Imperial Cancer Research Fund.

We regret to announce the death of Bertie Ronald Gordon Russell, which occurred, after a short illness, on December 22nd, 1924. Dr. Russell graduated M.B., Ch.B. at the University of Aberdeen in 1904, and became M.D. in 1908. After serving as an assistant in the pathological department of the University, he came to London in 1906, and acted as voluntary assistant in the laboratories of the Imperial Cancer Research Fund. The following year he joined the scientific staff, of which he remained a member until his death. During the great war he served in the R.A.M.C. from 1914 to 1918, first at the Royal Herbert Hospital, Woolwich, and later in Malta.

Russell's scientific work was almost entirely confined to the study of malignant disease, and on this subject he was recognized among experts the world over as a sound and trustworthy experimenter and critic. His early work was concerned chiefly with the study of resistance to the growth of implanted fragments of tumours. This resistance may be natural or induced; the induced or artificial form follows inoculations of normal tissues, or, sometimes, is a consequence of the growth of a tumour graft. Russell demonstrated that the anatomical basis of the resistance is a failure on the part of the host tissues to supply a vascular framework around and upon which the implanted tumour cells may grow. The development of resistance, which may occur concomitantly with the growth of implanted fragments of cancer tissue, was investigated with great care by him. It was a task which demanded an extraordinarily high standard of skill—operative, experimental, and histological. Few could have been found equal to the demand, but Russell succeeded in this work, and showed that differences between tumours in the power of inducing resistance are very great, and that the influence of the host tissues—"the soil"—is of little importance. In later work he was occupied with the comparison of the metabolic processes—the oxygen requirements, the powers of utilizing sugars, and so on—of normal and malignant tissues. The object of the work was to discover some measurable difference, apart from the fundamental difference in growth energy, between cancerous and normal cells. This work was still in progress at the time of his death.

For many years Russell was interested in the malignant transformation of the stroma of certain carcinomata. It

was for a long time the only method known of producing a new malignant growth. One carcinoma in particular which he studied was able regularly, on about the ninth week of its growth, to cause the connective tissue stroma, which is provided by the host, to develop into a sarcoma. It was natural, therefore, when it had been shown by Yamagiwa and his colleagues that tar, applied repeatedly to the skin, will induce a carcinoma, that Russell should attempt to induce a sarcoma by the same means. In this he succeeded.

In all his work Russell was very thorough and painstaking; his attention to detail saved him much labour. But it was in the difficult art of experimentation that he excelled; his judgement in the "lay-out" or disposition of an experiment enabled him to obtain answers to questions with a surprising economy of materials. As a colleague no man could have been more admired and respected. His learning, which was vast, was at the disposal of all; his kindness and patience were apparently limitless, whilst good humour, in good times or in bad times, never failed him. In public scientific controversy he would take no part, but delighted in the controversy or argument which is inevitable in a research laboratory; he was a very formidable but always scrupulously fair opponent in such discussions. To his friends he was a most lovable man, loyal, and charitable to weaknesses. He bore long-continued ill health with a courage and patience which formed a part of his strong character.

W. E. G.

**JOSEPH MANSERGH PALMER, F.R.C.S.I., M.R.C.P.I.,**  
Surgeon, County Armagh Infirmary, Armagh.

THE announcement of the death, on December 21st, 1924, of Dr. Palmer at his residence, Infirmary House, Armagh, will be received with much sorrow by the profession in Northern Ireland, and by a very large circle of private friends and patients. Dr. Palmer was 74 years old, and had been connected with the County Infirmary of Armagh for over fifty years. His professional attainments were of a high order, and his skill in operative surgery was well known. Dr. Palmer was one of those busy men whose services are sought for by all around. He had been president of the North of Ireland Branch of the British Medical Association, and formerly was a very constant attendee of its meetings. He was visiting and consulting physician to the Armagh Lunatic Asylum; consulting physician to the "Retreat," Armagh; physician to Shiell's Institute, Armagh; and held many other posts; he was also D.L. and J.P. for the county, and had held the office of high sheriff in 1906.

Much sympathy is felt for his widow and family, many of whom played a distinguished part during the war, both in the army and in the navy.

**DR. ERNEST ALFRED EDELSTEN**, who died on December 18th, 1924, at his residence in Streatham, aged 63, was educated at the Boteler Grammar School, Warrington, New College, Oxford, and St. Bartholomew's Hospital. In 1884 he graduated B.A., with honours in natural science, and four years later won the Bentley surgical prize at St. Bartholomew's Hospital. In 1889 he obtained the M.R.C.S.Eng. and L.R.C.P.Lond. diplomas and the M.A., M.B., and B.Ch. degrees. His first appointment was that of house-surgeon to the East London Hospital for Children, Shadwell, and he afterwards served as house-physician and assistant house-surgeon at the York County Hospital. After a short period of general practice in partnership at Shirley, Southampton, he removed, in 1896, to Brixton. For the last four or five years, owing to ill health, Dr. Edelsten accepted no new patients, only keeping on the old ones, by whom he was very highly regarded. He spent a total of thirty years in general practice. He served for some time on the Executive Committee of the Lambeth Division of the British Medical Association, and on the committees of local medical societies. He took a considerable interest in post-graduate work. Since 1907 he had been an enthusiastic motorist, and until the beginning of the war was actively interested in golf and lawn tennis. He is survived by his widow and four children.

**DR. CHARLES JAMES PENTLAND** was killed outside his house in Gower Street, London, on December 21st, 1924, as the result of a collision between a motor car and a lorry. Dr. Pentland received his medical education at Trinity College, Dublin, and graduated M.D., B.Ch., B.A.O. in 1910. He was assistant physician to St. Mary's Hospital for Women and Children, Plaistow, and x-ray dermatologist to the Western Skin Hospital. He was a Fellow of the London Dermatological Society, and of the Society for the Study of Venereal Diseases. His previous appointments included those of medical officer to the Rowan Dispensary, to the Royal Irish Constabulary, and to Dr. Stevens's Hospital, Dublin. He had published articles on *Ascaris lumbricoides* infection in children, and on diabetes from the physiological standpoint. He was a member of the British Medical Association.

**DR. RICHARD HOLGATE SHAW**, who died on December 22nd, 1924, was born in 1868, and received his medical training at Leeds. In 1891 he obtained the diplomas of M.R.C.S.Eng., L.R.C.P.Lond. From 1892 to 1912 he was engaged in medical practice in Liversedge, Yorkshire, where he was medical officer of health and police surgeon. After a year or two of leisure he recommenced practice at Golders Green. He acted as medical officer of the Hampstead Garden Suburb Auxiliary Hospital from 1916 to 1919, and for his services there he was mentioned in despatches and awarded the M.B.E. He held the post of surgeon to the Southern Division of the Metropolitan Police from 1917, and also that of surgeon to the Post Office in Golders Green. He had been a member of the Executive Committee of the Bradford Division of the British Medical Association from 1906 to 1909, and from 1920 to 1923 he was a member of the Executive Committee of the Finchley and Hendon Division. Dr. Shaw was a man of strong personality, highly successful as a general practitioner, and most popular with his patients and colleagues. After his final retirement in June, 1923, he lived at Bournemouth. He married Louisa Marion, daughter of the late Dr. Francis Boynton-Lee of Liversedge, who, with two daughters and one son, survives him.

**DR. SARAT KUMAR MULLICK, C.B.E.**, one of the leading medical men in Calcutta, died there on November 30th, 1924. He was educated at Calcutta University, St. Mary's Hospital, and Edinburgh University, graduating in the latter as M.B. and C.M. in 1887, and as M.D. in 1905. He took a leading part in medical politics in India, and was an ardent advocate of military service for the Bengalis. During the war he raised the Bengali Ambulance Corps, which served successfully in Mesopotamia. He had a considerable share also in inducing the Government to enrol a Bengali battalion for combatant service. He received the C.B.E. after the war, in recognition of his work. He was president of the Indian Territorial Force Committee, and had just attended a meeting at Delhi on this subject when he was attacked, on the return journey to Calcutta, by pneumonia, which proved fatal in a few days. Dr. Mullick was professor of medicine and clinical medicine in the National Medical College of India; and physician to the King's Hospital, Calcutta, two purely Indian institutions. He was also editor of the *Medical and Surgical Journal of the Tropics*, Calcutta.

## The Services.

### DEATHS IN THE SERVICES.

**Lieut.-Colonel George Augustus Emerson**, Bengal Medical Service (ret.), died at Parkstone, Dorsetshire, on December 27th, 1924, aged 72. He was born at Dinapur, and was the son of Lieutenant James Emerson, of the 26th Bengal Native Infantry. He was educated at Edinburgh, where he graduated M.B. and C.M. in 1876. He entered the I.M.S. as surgeon in October, 1877, reached the rank of lieutenant-colonel after twenty years' service, and retired on April 2nd, 1903. He served in the Afghan war of 1878-80, receiving the medal with a clasp, and in the Sudan campaign in 1885 at Suakin, gaining the Egyptian medal with two clasps, and the Khedive's bronze star. In this campaign, when the dervishes made a sudden attack on the British force as it was making camp, Emerson's regiment, the 17th Bengal Infantry, or Loyal Poorbeahs, was the one which was first attacked, and suffered very severe losses, their commandant, three other officers, and some 150 men being killed. The action is known by the name of Tofrek, or Baker's zariba.

## Universities and Colleges.

## UNIVERSITY OF LEEDS.

## HONORARY DEGREES.

THE celebrations in connexion with the jubilee of the Yorkshire College of Science and the coming of age of the University of Leeds were described in our issue of last week, and it was mentioned that the University had taken the opportunity of conferring honorary degrees on a number of distinguished persons, including the Earl of Balfour, Chancellor of the University of Cambridge; Sir Michael Sadler, formerly Vice-Chancellor of the University of Leeds; Sir Berkeley Moynihan; and Dr. J. E. Addison, formerly professor of medicine in the University.

In presenting Sir Berkeley Moynihan, the Vice-Chancellor recalled that he had been a student of the Leeds School of Medicine, that he had been connected with Leeds General Infirmary during the whole of his professional life, and that he had been elected in 1909 to the chair of clinical surgery. It had been Sir Berkeley Moynihan's privilege and pride to enhance the prestige of the school. During the great war he had been consulting surgeon to the Northern Command, and chairman of the Army Medical Advisory Board (an office he still retained). His office as teacher of surgery had enabled Sir Berkeley Moynihan to bring into play the magnetism of a rare personality, stimulating, suggestive, inspiring, vigorous, and lofty-minded. He had insistently urged upon his students that the first duty of a surgeon was to make use of every available source of knowledge to place the patient in the right position for recovery. His brilliant technique, his imaginative resourcefulness, his splendid courage, his delicate manipulative power, were the admiration of his professional brethren.

In presenting Dr. J. E. Addison (who was not able to be present), Professor Wardrop Griffith said that the name of Emeritus Professor John Edwin Addison would always be remembered by those who had watched the development of the University of Leeds. He had been a member of the council of the Yorkshire College from its earliest years; he had succeeded Sir Clifford Allbutt as professor of medicine, and he had taken a great part in the work of the Leeds Literary and Philosophical Society; he had also for some years been its president. Between that society and the University there had always been a close connexion. Dr. Addison had served on the full staff of the General Infirmary from 1871 to 1892, and during all that time was actively engaged in teaching. As a teacher he was critical and suggestive rather than merely didactic, and probably the full and true value of his teaching was appreciated by his pupils only after they had been some years in practice.

## UNIVERSITY OF DURHAM.

AT the convocation held on December 20th, 1924, the following degrees were conferred:

M.D. (for Practitioners of Fifteen Years' Standing).—P. Henderson, E. G. D. Nilsson.  
M.B., B.S.—Elizabeth M. Dorothy J. Brown, A. Fairlie, J. Hamilton, R. B. Holme, H. V. Ing.

## UNIVERSITY OF ST. ANDREWS.

A MEETING of the Senate was held on December 20th, 1924, when Dr. W. L. Burgess and Dr. David Lennox were appointed Lecturers in Public Health and Forensic Medicine respectively. Professor E. P. McLoughlin, Professor of Anatomy, University College, Dublin, was appointed an additional examiner in anatomy and medicine, and Dr. Alexander was appointed examiner in surgery for the Diploma.

## QUEEN'S UNIVERSITY, BELFAST.

AT the meeting of the Senate on December 23rd, 1924, Sir William Whitla, M.A., M.D., D.Sc., was appointed Pro-Chancellor. Dr. John A. Milroy was appointed "J. C. White" Professor of Biochemistry, and Dr. Victor D. Addison "J. C. White" Lecturer in Bacteriology.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following candidates have been approved at the examinations indicated:

PRIMARY FELLOWSHIP.—J. J. Walsh.  
FINAL PROFESSIONAL FELLOWSHIP.—R. H. J. M. Corbet, G. E. Strahan, and W. E. C. Wynne.

## CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examinations indicated:

FINAL PROFESSIONAL EXAMINATION.—J. J. Bourke, A. F. Cook, T. F. Crean, T. A. Cronhelm, J. Dalrymple, E. J. A. Dugan, Mary J. Fagan, E. M. Flanagan, E. C. Gray, T. T. Joyce, C. Keating, M. G. Kelly, A. B. Kennedy, Wilhelmina C. Maguire, J. C. Murphy, Mary J. McDermott, Mary E. Nelson, T. J. O'Connor, C. E. A. O'Riordan, A. Owen Flood, J. H. Owen Flood, P. C. Raftery, T. C. Stedley, R. Taylor, T. W. Wilson.  
D.F.P.R.—Marianne H. Hoskin, Kathleen O. M. Kennedy, J. F. O'Connor, M. Sayers.

## SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SENIORE.—A. H. Allam, D. T. Jenkins, A. Mistry (Section B), J. Wilson.  
MIDWIFE.—S. W. Coff, D. T. Jenkins, T. McD. Kellough, F. R. Khatnagar, C. C. Taff, R. D. M. Tims.  
FORENSIC MEDICINE.—C. L. Copeland, T. G. L. Davies, R. Norrie, K. Samra, P. H. Steele, W. T. Swanton, C. C. Taff, R. D. M. Tims, C. W. Warner.  
MIDWIFE.—W. T. Swanton.

The diploma of the Society (L.M.S.S.A.) has been granted to Messrs. K. Samra, W. T. Swanton, and R. D. M. Tims.

## Medical News.

AS will have been seen in the newspapers this week, Dr. C. Courtenay Lord showed much courage and resource in his efforts to rescue a party of motorists whose car fell into the river Onny, near Craven Arms, in Shropshire, during the Christmas holidays; he succeeded in saving the lives of two people, and with great difficulty pulled a third (who died later) out of the flooded river. Dr. Lord is Assistant Medical Secretary of the British Medical Association.

THE arrangements for the next social evening, on January 19th, of the Royal Society of Medicine have been altered. The guests will be received by the President, Sir St. Clair Thomson, at 8.30 p.m., and at 9.30 Miss Lena Ashwell will give an address entitled "The Drama as a Necessity of Civilized Life."

REGULAR interchange of information is a notable feature of modern effort to control infectious disease. In England, for the use of medical officers of health and all others interested, the Registrar-General issues weekly and quarterly returns. There is, besides, for the confidential guidance of port health officers, a weekly record of infectious diseases at ports at home and abroad. Recently we called attention to the international action taken by the League of Nations in publishing annual reports of infectious diseases in many lands in every quarter of the globe, as exemplified in the volume for 1923. But note should also be taken of the monthly issue of similar reports in French and English. These contain in addition to tables of statistics, charts, etc., a general summary calling attention to the salient features of disease prevalence; the reports are on sale by authorized agents throughout the world. For Britain the agents are Constable and Co., Ltd., 10 and 12, Orange Street, London, W.C.2. The annual subscription is 10s., and the price per number is 1s.

AT the general meeting of L'Union des Syndicats Médicaux de Franco, held at the end of November, 1924, it was decided after a long discussion that the co-operation of the Syndicats Médicaux with the proposed insurance legislative measures would only be possible if the following conditions were accepted: Free choice of doctor, and strict professional secrecy; fees payable on a basis of visits, either according to a tariff regulating the financial responsibility of the State, but not limiting the actual amounts chargeable, or by arrangement between the medical practitioner and his patient, possibly in accordance with some agreement between the medical associations and the Government. With reference to the proposed new taxation a resolution was adopted that the medical practitioner should not be assessed on his apparent income without regard to his expenses; and that no new tax should be imposed on sickness by classifying medicinal preparations as luxuries. It was added that the medical staffs of hospitals should not be taxed.

THE late Lord Abercrombie, who was himself a distinguished authority on prehistoric archaeology, bequeathed to the University of Edinburgh a sum of £17,000 to found a chair in that subject. He also bequeathed to the University certain books to form the nucleus of a special section of the library, together with any other of his archaeological and anthropological books and photographs that the library committee of the University might select.

THE seventh Congress of the International Society of Surgery will be held in Rome from April 7th to 10th, 1926, when the following subjects will be discussed: Radium therapy of cancer of the uterus, treatment of cerebral tumours, surgery of the spleen, abscess of the liver, remote results of the treatment of Jacksonian epilepsy. Further information can be obtained from the Secretary, Dr. L. Mayer, 82, Rue de la Loi, Brussels.

THE new medical school building attached to the Hangchow Mission Hospital, which was opened at the beginning of October, 1924, is a combination of Chinese and foreign architecture, and provides an educational establishment on the most modern lines. On the ground floor is a large assembly room, four smaller lecture rooms, three laboratories

for physics and chemistry, and a museum. On the first floor there are two more lecture rooms, accommodation for the medical staff, and laboratories for biology, histology, and pharmacology, together with a library and reading room. The pharmacology laboratory contains two lines of steel drums, driven by an electric motor, for recording muscular action. The third floor of the building provides dormitories for seventy-five students, and there is additional accommodation in the old building for sixty. The old building also has a lecture hall for seating 1,000 students, and is fitted with a cinematograph. The medical school is attached to a hospital containing 500 beds and dealing with nearly 40,000 patients annually.

THE Joint Nursing and Midwives' Council of Northern Ireland, being about to revise its list of examiners, invites applications from registered medical practitioners, including women, who would be willing to act. Particulars can be obtained from the Registrar, 118, Great Victoria Street, Belfast, to whom applications should be sent not later than January 15th.

THE Harben Lectures of the Royal Institute of Public Health will be delivered at its house (37, Russell Square, London, W.C.) by Dr. Edgar L. Collis, professor of preventive medicine in the University of Wales. The subject of the course is phthisis and industrialism (national and occupational), with reference to other infectious diseases. The lectures will be given on January 26th, 27th, and 28th at 4.30 p.m. on each day. The lectures are open to the public.

POPULAR science lectures in aid of King Edward's Hospital Fund (7, Walbrook, E.C.4) will be delivered during the first three months of 1925, at various centres in London. The lectures will deal chiefly with scientific discoveries and achievements in recent years in the departments of biology, physics, chemistry, and physiology; they will be illustrated by experiments and demonstrations, or by lantern slides.

A SESSIONAL meeting of the Royal Sanitary Institute will be held at the Town Hall, Newcastle-on-Tyne, on Friday, January 16th, when, with Professor H. R. Kenwood, C.M.G., M.B., in the chair, a discussion on maternity and child welfare practice will be opened in critical papers by Dr. A. F. G. Spinks and Mr. H. Harvey Evers, M.S., F.R.C.S., at 4 p.m. Other papers will be read in the evening. On Saturday visits will be paid to the maternity and child welfare centre, to a maternity hospital, to a model dairy, and to the new public baths.

A HOSPITAL, health, nursing, and midwifery exhibition and conference will be held at the Central Hall, Westminster, from April 20th to 24th. The railways have consented to issue tickets at the single fare and a third for the return journey. Further particulars can be obtained from the Organizing Director, 12a, Belsize Park Gardens, London, N.W.3.

THE issue of *Nature* for this week (January 3rd) will contain an article by Professor E. H. Starling on the scientific work of Professor I. P. Pavlov. It will be accompanied by a photographic plate portrait suitable for framing.

### NEW YEAR HONOURS.

THE New Year's honours list contains the following names of members of the medical profession:

#### K.C.V.O.

HENRY JOHN FORBES SIMSON, M.B., C.M., F.R.C.S.Ed., Surgeon to the Hospital for Women, Soho Square, and Obstetric Surgeon to the West London Hospital.

#### Knighthood.

JOHN CAMPBELL, M.Ch., F.R.C.S., LL.D., Senior Surgeon to the Samaritan Hospital for Women, Belfast, and the representative of Queen's University in the Northern Ireland Parliament.

FREDERICK GOWLAND HOPKINS, D.Sc., M.B., F.R.C.P., F.R.S., Professor of Biochemistry in the University of Cambridge.

THOMAS MORISON LEGGE, C.B.E., M.D., Senior Medical Inspector of Factories, Home Office.

HOLBURN JACOB WARREN, C.B.E., M.S., F.R.C.S., Senior Surgeon, St. Bartholomew's Hospital, and Vice-president of the Royal College of Surgeons of England; Vice-Chancellor of the University of London, 1922-24.

Major-General ROBERT CHARLES MACWATT, C.I.E., M.B., F.R.C.S., Director-General Indian Medical Service.

FREDERICK TRUBY KING, C.M.G., M.B., Director of Child Welfare, New Zealand Department of Health.

#### D.B.E.

Miss LOUISA B. ALDRICH-BLAKE, M.S., M.D., Dean of the London School of Medicine for Women.

#### C.B. (Military).

Major-General S. F. ST. DAVIDS GREEN, C.B.E., M.D., D.D.M.S., Western Command, India.

Major-General H. J. K. BAMFIELD, D.S.O., I.M.S., D.D.M.S., Eastern Command, India.

#### C.M.G.

W. J. J. ARNOLD, M.B., Colonial Surgeon, St. Helena.

#### C.I.E.

Colonel C. H. BENSLEY, I.M.S., Inspector-General of Civil Hospitals and Prisons, Assam.

Lieut.-Colonel E. C. G. MADDOCK, I.M.S., late Civil Surgeon, Poona.

Lieut.-Colonel J. C. S. VAUGHAN, I.M.S.(ret.), Superintendent Radium Institute, Ranchi.

#### Kaiser-i-Hind Medal.

S. C. HORMUSJI, M.D., First Assistant Health Officer, Bombay.

HENRY T. HOLLAND, M.B., F.R.C.S.Ed., Medical Officer of the Church Missionary Society, Baluchistan.

Mrs. GRANT STAIR, M.D., American Baptist Mission, Udayagiri.

Other birthday honours of interest to the medical profession are the Order of Merit awarded to Sir James Frazer, author of the *Golden Bough*, and to Sir Ernest Rutherford, pioneer investigator of radio-activity and the constitution of the atom; and the knighthoods conferred on Mr. W. B. Hardy of Cambridge, Secretary of the Royal Society, and on Mr. Edmund Gosse, who delivered the first Lloyd Roberts Lecture at the Royal College of Physicians, on personal relations between medicine and literature (BRITISH MEDICAL JOURNAL, November 24th, 1923, p. 999).

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication.

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager, 429, Strand, London, W.C.2. Attention to this request will avoid delay. Communications with reference to editorial business should be addressed to the Editor, BRITISH MEDICAL JOURNAL, 429, Strand, W.C.2.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange). The telegraphic addresses are:

EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London.

MEDICAL SECRETARY, Mediscera Westrand, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361, Central).

### QUERIES AND ANSWERS.

#### INCOME TAX.

##### Cost of Repairs and Improvements.

"H. G. S." inquires: Can I deduct the cost of doing up my treatment rooms, such as laying new floors, putting up partitions, and the cost of electrical instruments?

\*. The same principle governs both classes of expenditure—namely, that the cost of improvements or of adaptations for special purposes represents capital outlay and cannot be deducted for income tax purposes. But in so far as the expenditure covers ordinary repairs it is deductible—for instance, if the floor in question was in such a condition as to make it advisable to replace it, then the cost of putting in the same sort of floor would be allowable, but not any extra expense incurred because a different or improved form of flooring was desired; similarly the cost of installing an electrical equipment is not allowable, but the expense of maintaining the apparatus in working order is deductible.

#### AGED BLIND.

"H. R."—Information regarding institutions where aged blind may be received into residence may best be obtained by application to the Secretary of the National Institute for the Blind, 224, Great Portland Street, London, W.1. The activities of the institute cover all parts of the country; it has local agencies and works in association with local societies for the blind. Since the inquiry comes from Buckinghamshire, communications might also be made to the Secretary of the Buckinghamshire Association for the Blind, Lindford Hall, Wolverton.

#### TREATMENT OF GOITRE BY IODINE.

DR. G. W. JOSEPH (Prestatyn, North Wales), in reply to Dr. McAskie (December 27th, 1924, p. 1216), writes to say that he has supplied details to all medical practitioners who have made personal application to him.

## LETTERS, NOTES, ETC.

## ALLONAL.

"M.R.C.S., L.R.C.P." writes: I wish to add my warning to that frequently given by Sir William Wilcoxon in regard to veronal allonal and all other veronal compounds. I have seen to my grief and misery the effects of allonal on a dear one when on his death-bed. If I can be of use in warning fellow medical men I shall feel happier. Small doses of heroin, as recommended by Sir William Wilcoxon, or, if I may give my own experience when dangerously ill, doses of morphine and atropine, will bring relief without the dreadful mental distress which is brought about by veronal allonal and other veronal types of hypnotic. Morphine and atropine is a kindly thing and a blessed thing, and if anyone reading this has a dear one hopelessly ill I ask that my bitter experience of this dangerous drug allonal be acted upon.

## HYPERPYREXIA IN INFLUENZA.

DR. J. ROBERTSON HALL (Fence Houses, co. Durham) writes: I have just attended a case, which unfortunately proved fatal, of influenza with so unusually high a temperature that I think it worth recording. The patient was a married woman, aged about 42, with three children, the youngest about 2 years. She was not pregnant when she died. She had a very severe attack of influenza with a high temperature, on an average about 104° F. for the first four days. On the morning of the fifth day after I was called in, I was sent for about 6 o'clock, and on arrival found her in a serious state, with a temperature of 110° F. Needless to say, she did not live long—in fact, she died in less than an hour after the temperature was taken by me. I could discover no evidence of pneumonia and her breathing was never difficult, but all through her illness she complained of severe headache. The really remarkable point, in my view, was the extraordinarily high temperature of 110° F. In seventeen years' experience of busy industrial practice I have never come across so high a temperature before.

\* The fact that hyperpyrexia may occur in influenza is noted in some of the textbooks, but it seems to be a rare occurrence.

## DERMATITIS HERPETIFORMIS GESTATIONIS.

DR. C. H. S. HOWRITZ (Sireatham, S.W.) writes: The following case is of interest because of the rarity of the complaint and the severity of the skin eruption: Mrs. X, aged 19, a primipara, had been perfectly well. On awakening in the morning three days before the birth of her child she noticed one or two "spots" on her face and neck. She had never previously had any skin affection to her knowledge. My attention was called to the eruption during the day, and I was struck with the similarity it bore to the rash of chicken-pox, with the exception that the vesicles were round instead of oblong. She felt quite well; the temperature was not raised and the pulse was normal.

Several hours later she presented a severe morning eruption on the neck, chest, and abdomen. The knees were covered with an inflammatory, superficially seated, multifocal, vesicular eruption. Upon pressure the vesicles easily ruptured and exuded a clear serum. The vesicles varied in size from a pin's head to a pea. She complained of intense itching. I judged the condition to be due to some toxic condition, caused, I thought, by the presence of the child, and I felt fairly confident that after the birth all would be well. With the birth of the child the source of the toxins would be removed, I argued, and I was able to reassure the parents, who were naturally very concerned about their daughter's appearance.

I ordered arsenic internally and gave great relief from the itching. After the birth there were no more fresh eruptions and the vesicles rapidly commenced to dry up and scab. In forty-eight hours all irritation had ceased, and in a few days nearly all signs of the eruption had vanished. The distribution of the rash—about the face and arms on the second day of the occurrence—was not at all unlike small-pox. The child was not affected.

## POISONING BY POTASSIUM CYANIDE.

THE following case is reported by Dr. JOHN REID and Mr. JOHN KENNEDY of Ashford, Middlesex: In the early morning one of us was called to see a man who was stated to be unconscious in bed, and supposed to have had a fit. The man, aged about 60 years, was completely insensible and deeply comatose, with hands clenched, the eyes fixed, staring, and completely insensible to light, and the muscles of the limbs relaxed and flaccid. There was froth on the mouth, the breathing was slow, deep, and convulsive, the pulse very quick and almost imperceptible. It was obviously a case of poisoning. On searching we found a packet of potassium cyanide inside the pocket of his coat, which we placed; 15 to 20 grains had been swallowed by the silver vessel having been used. As we expected, the usual treatment, injection of camphor oil, strychnine, and atropine, and artificial respiration, was of no avail, and death ensued in an hour and twenty minutes. At no time was there any reaction to treatment. There were no convulsions before death. Death was due to asphyxia, as the heart continued to beat for a considerable time after respiration had ceased.

## NITROUS-OXIDE-OXYGEN ANAESTHESIA FOR MAJOR OPERATIONS.

DR. CHARLES T. W. HIRSCH (London, S.W.) writes: The recent remarks of coroner and pathologist at an inquest on an unfortunate fatality should, I suggest, not be passed by anaesthetists without protest. The impression given by the coroner was that nitrous oxide was an anaesthetic for dental operations only, and the pathologist seemed of the same opinion—that for long operations unconsciousness could not be maintained with nitrous oxide if oxygen was given, and that if the latter was not administered suffocation occurred. As an anaesthetist on the staff of eight hospitals I desire to enter my protest against this scathing condemnation of the value of nitrous oxide-oxygen in major operations. I have administered that anaesthetic in many cases; I have had it myself on five occasions. I submit that it is a most useful and valuable anaesthetic, and though for certain abdominal operations I admit it may not alone give all the relaxation the operator might desire, still, with a little bubbling through ethanest, the relaxation needed can always be had. Even if thus a small amount of ethanest is employed, that is preferable, from the patient's point of view, to an anaesthesia solely procured by ether or ethanest. The little that may have to be used rarely produces any post-anaesthetic effects.

## NASAL NEUROSIS.

DR. CHARLES J. HILL AITKEN (Kilnburst, near Rotherham) writes: Dr. Neil MacKay states in his article (*BRITISH MEDICAL JOURNAL*, November 29th, 1924) that after a dose of guanidine "increased vascularity in the nose was noted, as well as an increase of mucus, and each animal performed active chewing movements and nose rubbing." Some years ago I was much bothered at sick parades by a delicate-looking man whose complaints were so curious and so varied that I labelled him a case of *psyllosthenia* (Purves-Stewart, *Diagnosis of Nervous Diseases*). One day it struck me this man had nasal obstruction and that he was a mouth-breather. Examination proved I was right. I taught him to breathe through his nose. And I not seen cases of children who had had adenoids removed showing wonderful results I would have been surprised at the patient's rapturous declarations of the change in his outlook on life. Some months later this formerly poor complaining individual told me he had had one symptom he had not confessed to me. This symptom was attacks of gluttony. He asked me now to explain how he never, except very occasionally, had such attacks. Experiment showed that excessive appetite was present when the nose became blocked during a meal. By experiment we induced this blockage and the patient wolfed down his food. I painted the anterior part of the vascular mucosa with a weak solution of cocaine. Shortly after the patient said, "Take away this food, I don't want it." His nose had cleared and synchronously his appetite failed. The explanation I gave was this. Purves-Stewart states:

"A certain amount of ... supports the view that there is a ... the sensations of hunger ... temporal lobe, at or near the ... tumours in this region have ... (Page 47 *ibid.*)"

In the case I record there was no central lesion. There was, however, peripheral irritation in the nose and hence voracious appetite, which ceased the instant the nasal passage was opened up and pressure removed.

## "A RICH SAMPLE OF MILK."

DR. H. D. BISHOP (States M.O.B., Guernsey) writes: I recently purchased for analysis in the ordinary way a sample of milk from a small shop in Guernsey. The analysis showed: Total solids, 15.21; fat, 6.9; solids not fat, 9.31; and cream, by volume, 26 per cent. I naturally thought that this milk must be either mid-day, afternoon, or "strippings," but upon investigation found that it was morning's milk and the mixed yield from a herd of twelve Guernsey cattle.

## A WARNING.

DR. HUBERT COX (Edgbaston) has been informed that an individual has been making use of his name and address in the Luton district for the purpose of obtaining money from doctors. He desires to put doctors on their guard. It is suggested that any practitioner receiving a visit from such a person should communicate with the police.

## BRIDGE OF WEIR SANATORIUM.

THE second issue of the *Bridge of Weir Sanatorium Christmas Magazine* is a matter for congratulation. The editor and the various contributors have produced an interesting, amusing, and well illustrated magazine, which should win the approval of those for whom it is written, and contribute to the establishment of the hopeful spirit, the importance of which is emphasized in a foreword by the medical superintendent, Dr. James Crockett.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 32, 33, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 34 and 35. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 16.

## A Post-Graduate Address

ON

HEART AND AORTA STRAIN AND  
"LYING-DOWN HEART."

BY

E. M. BROCKBANK, M.D., F.R.C.P.,

HONORARY PHYSICIAN, THE ROYAL INFIRMARY, MANCHESTER.

I HAVE chosen the subject of heart strain because it is one which has to be considered by medical men at the present time under a variety of aspects, in our private work and in compensation claims. As I think strain of the aorta may occasionally enter into the question too I have included it, and will give my reasons for doing so at a later stage.

*Definition.*

By heart strain I mean the sudden development of subjective signs of cardiac muscle failure which can be attributed to some unusual muscular effort, even though the effort was one which ought not to have had such a result in a healthy person.

The chief subjective symptoms of heart strain are pain over the region of the heart or behind the sternum, exactly like, or simulating, true angina pectoris, and shortness of breath on slight exertion. The objective signs are some dilatation of the heart with extension of dullness to the left, signs of valvular disease, feeble sounds or gallop rhythm, and a quick pulse rate with manifest shortness of breath on slight effort.

*Compensation Claims.*

Heart strain is often made the basis of a claim under the Workmen's Compensation Act, and such a claim was also common at the pensions boards set up after the war. The danger of heart strain occurring in workers who are known to have something wrong with the heart has not infrequently to be considered at the worker's or employer's request. This leads me to refer at once to a most important point in connexion with the causation of disablement from accidents. An accident in the meaning of the law is "an unforeseen or unexpected occurrence arising out of or in the course of employment."

The point I wish to emphasize here is that compensation for incapacity or death must be paid even if the injured worker has had some chronic disease or weakness, such as heart disease, arterio-sclerosis, aneurysm, or high blood pressure, which rendered him liable to suffer serious disablement or death from an "accident" which would have had no serious result in a healthy sound worker. This interpretation of the meaning of an accident caused a revolution in the decisions of the courts administering the Workmen's Compensation and Employer's Liability Acts, and consequently in the whole matter of claims for accidents.

The guiding case on accident claims is that of a man who, when tightening a nut with a spanner, finding it stiff, and making an extra hard effort to move the nut, burst an aneurysm and died. This was held by the House of Lords to be an accident, and this decision governs all analogous claims, the unexpected and unforeseen circumstance, I am told, being the bursting of the aneurysm, not the extra effort.

At present few employers or insurance companies require medical examination before engaging a workman, but the increased sums to be paid under the Compensation Act of 1923 for disablement—£600 lump sum instead of £300 and 30s. a week for life instead of 20s.—may lead to it, especially in elderly men and women. This, however, is a by-path and I will leave it.

*Strain of Healthy Heart.*

It is a much discussed question whether sudden muscular effort involving a heavy strain on the heart can produce muscle failure or valve injury in a healthy heart or valve of a normal person. I had the experience lately of some cases which at first led me to think that this could happen, if we were to believe the statement of apparently honest

steady men as to a history of accident or of venereal disease. But final investigation and clinical tests put a different complexion on the cases, and I formed the conclusion that I had seen no case of strain in a healthy person. This conclusion falls in with that of the physiologists, as stated by Bainbridge in his *Physiology of Muscular Exercise* (p. 200): "There is no evidence that in a perfectly healthy man, even the most intense exertion produces any harmful effect on the heart."

*PREDISPOSING CAUSES OF HEART STRAIN.*

All the cases of heart strain in my own experience have arisen through some latent weakness of the cardio-vascular system which has predisposed it to give way under strain which would not have affected a normal system.

I propose to consider the commoner predisposing causes of heart strain, and will take them in their relative order of frequency in my own practice. These are high blood pressure, valvular disease, syphilitic aortitis, and the senile heart. I will refer also to auricular fibrillation in its relation to heart strain.

*High Blood Pressure and Angina.*

The commonest form of heart strain I meet with is that caused by prolonged high blood pressure, the presence of which has probably not been known or suspected until shortness of breath or pain in the chest forces a visit to the doctor. This is also the commonest cause of angina pectoris, both in men and women, in my experience.

The heart in high blood pressure strain, with or without anginal pain, is considerably enlarged outwards towards or into the axilla, and the sounds are either feebly accentuated or there is gallop rhythm. There may be a murmur of mitral incompetence. The history is generally that of untireable activity in business or household work, then more or less sudden onset of bad shortness of breath or pain or both. When the breakdown has been apparently sudden it is quite likely that careful inquiry will show that there have been previous warnings, extending over a year or more, of slight pain and shortness of breath which the subject, unused to any shortcomings of health or power, thought could be worked off by extra effort.

Nature responds to the increased demands on the heart by laying down more heart muscle, and good compensation results, even if the heart has to be enlarged to twice or thrice its normal size. Life goes on until one of two things happens.

(1) The heart *gradually* becomes unable to do the work demanded from it and it shows signs of muscle failure, with breathlessness and perhaps pain. A common type of this event is the following case.

A lady, aged 73, sent for the doctor because she had a smothering feeling in the chest, shortness of breath, and pain behind the sternum, up the neck, and down the arms—typical angina pectoris. I was asked to see her eight weeks after she had called her doctor in. I found a systolic blood pressure of 180 mm., and the heart was about twice its normal size, with gallop rhythm. I was informed that she was a tireless worker at home and with manifold outside charitable interests. On pressing for the date of the onset of the first appearance of any discomfort I found that twelve months previously she had begun to have slight pain in the chest and shortness of breath on walking, but had said nothing about it to anyone. She had managed to get on with her work in a restricted way until the final breakdown.

(2) The heart *suddenly* fails under the stress of unusual muscular effort, often that of hurrying to catch a train, as happened in the following instance.

Mr. H. B., a business man, had worked hard for years at his own and public business, never getting tired. One day, when hurrying for three-quarters of a mile to catch a train, he became very distressed in his breathing, with oppression round the heart, and could hardly get along the last one hundred yards. The discomfort gradually eased off in the train, but he felt it again next day when walking to business. The pain was then shooting down both arms. When I saw him on February 20th, 1923, his systolic pressure was 200 mm. There was no arterio-sclerosis. The heart was enlarged, the apex extending to an inch further to the left than the normal and the sounds were accentuated. There was no albumin, sugar, or polyuria. At 48 he passed Grade I for the army. He was a lifelong abstainer from alcohol. He improved considerably under diathermy.

Here, I think, we had a heart that had been used to overwork for years, and had enlarged by good hypertrophy, but which was not able to stand the additional strain of a

rush to the station, and lost its compensation or failed suddenly. Rushing for trains, with the final dash upstairs—so many stations are above the level of the road—is responsible for many cases of heart strain, not only in subjects of high blood pressure, but in those with a senile heart.

*Treatment.*—I invariably treat these cases of heart strain in high pressure, especially those with the gallop rhythm, with digitalis, and with great benefit. Digitalis strengthens the failing heart muscle, and it does not increase the high pressure. Nitrites can be given as well, but the digitalis is essential. Less muscular effort, light and small meals, also are necessary.

#### Valvular Disease of the Heart.

*Aortic valvular disease* in the form of slight obstruction from roughened valve curtains without incompetence and with no dilatation of the heart or sign of muscle failure, is compatible with manual labour. Many elderly workpeople have it. I found it in one man, a mill hand of 79. He was then too old to work. Such a slight aortic valve change is not likely of itself to induce muscle failure, but its presence is an indication of atheroma and degenerative changes which may implicate the coronary vessels and so weaken the heart. Actual stenosis of the valve with thrill at the base may, in time, lead to heart failure. I remember a man about 40 years of age who fell dead from a telephone pole; his body was brought to the infirmary, and we found he had extensive stenosis of the aortic valve with much compensatory hypertrophy of the left ventricle; why he died we could not say.

#### Aortic Incompetence.

No one with aortic regurgitation should undertake manual labour, because this is the most dangerous of all valvular lesions, and for two reasons. The first is that when the aortic valves do not close completely there is not the normal amount of force to drive blood through the coronary arteries which arise from the aorta wall just above the cusps of the valve. The heart muscle, therefore, is inadequately supplied with blood and proportionately weakened. The second reason is that the pressure in the aorta, whatever it is, which drives blood through the incompetent valves, acts at its full strength on every part of the interior of the left ventricle of the same area as that of the leakage in the valve, and is not diffused all over the wall of the ventricle. In other words, if there is a force of 100 mm. of mercury acting on a valve leak of 1/4 inch square, there will be a force of 100 mm. acting on every square 1/4 inch of the ventricle, and not 100 mm. diffused all over the ventricle. This can be a very great degree of pressure, and, acting as it does on anaemic heart muscle, a sudden extra strain is very liable to cause paralysis of the heart and death from syncope, or to break down any existing compensation and lead to death from progressive heart muscle failure. I will mention one case in point.

I was asked to see a young man who had a sudden and unexpected strain arising in the course of his work—namely, hastily throwing a skip or basket containing cotton yarn, weighing 50 lb. or more, twenty feet along a floor, to save the time of a worker who was late in getting to the weighing machine where the skips were handed out. He felt a sudden pain in the chest and great breathlessness, and had to sit down. After a time he managed to get to the doctor, who thought he was dying, and kept him in his surgery for a couple of hours. Eventually he improved enough to get out of bed, and five months after the accident he came to see me to ask if I could attribute the condition of his heart to the accident. I found him very short of breath with marked aortic incompetence, and a heart about twice the normal size, with dilatation and hypertrophy and cardiac muscle failure—that is, broken compensation. I said that I could not attribute the whole condition of the heart to the accident described, but that the broken compensation had, in my opinion, been brought about by a sudden effort acting on a heart which had had aortic valve disease, especially incompetence, with consequent dilatation of the ventricle and some compensatory hypertrophy, for some time previously—a heart with no muscle reserve. The man eventually died in a few months, and the county court judge held that an accident had occurred which had hastened death.

I had one man with incompetence who was a motor driver, and I advised him to give this up. He dropped down dead when walking; fortunately not when driving a motor car.

It is very important to recognize aortic incompetence early, and this must be suspected whenever there is enlargement of the heart with moderate or normal rate of beat and when there is no increase of blood pressure. The diastolic murmur must be sought for carefully down the left margin of the sternum, even in the fourth intercostal space. There may be no obstruction with the incompetence and no murmur heard at the aortic cartilage.

#### Injury to the Aortic Valve.

I will now mention two instances of aortic valve affection which apparently were caused by unusual strain acting on an already diseased aorta.

A joiner, aged 42, joined the army in June, 1915, and was demobilized in April, 1919, without any medical examination, although he was short of breath on moderate exertion. He served in the Royal Engineers, and in 1918 felt a pain over the heart after lifting an unusually heavy balk of timber, and after this when the day's work was heavy. He also felt short of breath on marching from this time, but had no pain from walking. When I examined him in 1923 for a pension claim I found the apex to be in the fifth space and probably behind the sixth rib, and five and a half inches from the middle line—that is, two inches too far out. There was a musical squeak of diastolic rhythm to be heard all over the precordia and two inches away from the chest wall, without the aid of any stethoscope. A definite thrill was associated with the murmur. The nature, time, and area of audibility of the murmur were those of an aortic diastolic murmur, and the enlarged heart supported this diagnosis. He was passed as fit for service when he was examined by a recruiting medical board, and he had also been passed for insurance after medical examination before the war. His own doctor was sure that he had had no aortic disease before the war. The man said he had never had venereal disease, and I believed him. Here, I thought, might be a case of rupture or tearing of one of the cusps of a normal aortic valve causing incompetence of the valve, dilatation of the left ventricle, and compensatory hypertrophy, which was only partial because he was still breathless on exertion. A Wassermann test was carried out after a time at my request, and it turned out to be positive. There was therefore almost certainly some predisposing aortitis to weaken the valve.

A weaver, aged 36, in October, 1923, slipped whilst carrying a beam of warp yarn weighing 185 lb. on his shoulder, and was jammed between a pillar and a loom with the beam pressing on his chest. To get loose he had to lift the beam vigorously off his chest, and whilst doing so he felt something "go" inside his chest—like a finger cracking. He had no pain then, and continued at his work for five weeks, getting worse gradually, and then he had to give in because of pain and shortness of breath. I saw him in July, seven months after the occurrence. He then had shortness of breath and the pain at the base of the heart even on dressing himself. I found that he had a pulse of 120. The apex of the heart was four to four and a half inches from the middle line. When he lay down flat I heard a slight soft aortic diastolic murmur in the third intercostal space against the fourth rib. I could not be sure of the murmur when he was sitting or standing. There was no systolic aortic murmur. The second sound at the aortic area was ringing like that met with in aneurysm of the first part of the aorta, but there was no other sign of aneurysm. There was no change in the radial arteries, no increased blood pressure, and no albumin. It seemed to me that he had most likely strained the aorta and the ring of the valve, producing some dilatation of the first part of the aorta and incompetence of the valve. He said that he had had no venereal disease, and I again thought he was speaking the truth, but subsequent investigation showed a definitely positive Wassermann test. The leakage of the aortic valve was not sufficient, in my opinion, to cause as much dilatation of the heart as I thought was present, and so I came to the conclusion that he had probably strained the heart muscle as well as the aorta and brought on acute cardiac dilatation. He probably had some aortitis, and that predisposed the aorta and valve to strain. I was unable to get an x-ray photograph of the chest or an electro-cardiograph record of the heart's action.

These two cases of strain of the aortic valve under severe exertion are striking lessons on the importance of taking no one's word about venereal disease. I must say that I believed the men, and thought in both cases that the strain had come on in men who had not had syphilis.

*Aneurysm.*—Any person with aneurysm of the first part of the aorta would be very liable to injure the aortic valve and strain the heart by manual labour. The chances of an aneurysm bursting under such conditions are obvious.

#### Mitral Valve Disease.

Incompetence of the mitral valve—that is, with a systolic murmur—is the commonest valvular lesion in adult life. When met with after 50 years of age it is almost always slight in degree and unaccompanied by any heart muscle change of moment and has been present in stationary form for many years. I have found it in working men and women

over 68 years of age who did not know that there was anything amiss with the heart. Slight lesions occur in subjects with high blood pressure even at the same age. I have had carters, aged 53 and 45, referred to me by railway companies whose doctors had found loud systolic mitral murmurs and had certified incapacity. The men could not afford to give up work, and maintained ability to go on. There was a little cardiac enlargement, meaning good compensation, and no evidence of arterial disease or of muscle failure. The danger is the possibility of some extra exertion bringing on muscle failure and incapacity. A sudden event like this is not likely to occur with uncomplicated moderate mitral stenosis and incompetence. When the heart rate is normal and regular I generally let the men continue at their work and see them again in a month. If there is no change for the worse I recommend continuance of work which does not involve lifting of heavy weights. Men with such hearts would not get the disablement benefit of the National Insurance Act because they are able to do some work. One man I remember, in recruiting days, with a loud mitral systolic murmur and practically normal-sized heart, lifted 25 tons of pig-iron a day as part of his carting duties and felt no inconvenience.

#### Mitral and Aortic Disease.

All I could say in the following case was that army service had aggravated the heart condition.

A youth, aged 24, claimed disablement from war service. He enlisted at 15, was discharged on account of his age, and recruited again at 17. He was riding in the training camp when his horse bolted. He remembered nothing further until he found himself in hospital eighteen days afterwards. He had no rheumatism or its allied ailments. As a boy he had played games and managed physical drill all right. When in hospital his heart was found to be affected. He was in the army fifteen months only and never got beyond the training camp. I found that he had an enlarged heart extending 5 inches to the left of the middle line, and behind the sixth rib. There was a loud crescendo murmur with accentuated first sound typical of chronic mitral stenosis and a definite aortic diastolic murmur squeaking in character. Muscular compensation was good. I did not see how the accident could have brought on the valvular disease, especially the mitral stenosis, and there was no history in his army papers of any illness that could possibly have been rheumatic in nature. The valvular disease, especially that of the mitral valve, was almost certainly there on enlistment, although I could get no history of rheumatism in childhood.

#### Auricular Fibrillation.

Auricular fibrillation is a most important cause of serious heart-muscle failure, and its presence, either with or without valvular disease, contraindicates manual labour because effort makes it worse. At the same time a certain number of people work with it in its early stages before breathlessness comes on or before there is any indication of an abnormal heart. I have seen three people over 60 years of age claiming pensions with it, who were relieved of work at once. Auricular fibrillation is caused by failure of the auricular muscle, and it is conceivable that overexertion might bring this on in a weak auricle, but I have never met with a case in which fibrillation could be attributed to sudden strain, and at present I should be very unwilling to believe that such could happen. Auricular fibrillation is not uncommonly present, with or without organic valvular disease, without being suspected, and this fact would discount the value of its presence when recognized for the first time after a supposed accident.

#### Strain of Senile Heart.

By senile heart I mean a heart which is badly nourished because of atheroma of the coronary arteries or which has some fibroid degeneration—changes which occur in the later years of life.

A gardener, aged 62, used to mowing lawns, was delayed one day in trying to get a motor attachment to work. He failed to do so and had to push the machine, and unusually fast, to get the work done. He had an attack of palpitation and breathlessness with heart pain at night and all the next day, and had to give up heavy work, because of shortness of breath which came on when he made no effort. I saw him a month later, and found that his heart was a little enlarged and there was slight arterial sclerosis. His blood pressure was only 130. The pulse at the wrist was 64 and irregular, whilst the heart rate was 76. This meant

extra-systoles or auricular fibrillation, probably the former, for they are common at his time of life. He had ailed nothing before, but on being asked the question, said that for some years he had noticed his heart beating irregularly when he lay down in bed on his left side. Here, in my opinion, the man strained a senile heart muscle by unusually heavy exertion and had brought on some dilatation.

As I mentioned under high blood pressure a rush for a train at a railway station is not uncommonly the cause of the breakdown of a heart in older persons.

#### LYING-DOWN HEART.

Here is a case of pain of doubtful nature, but I wish to mention it because of a peculiar condition of the heart not uncommonly met with in people with intrathoracic pain.

E. W., wood machinist, aged 46, had had palpitation, shortness of breath on the least exertion, with precordial pains aching in character and occasionally very severe, on and off since 1917, when he was serving as a farrier in the army. He stuck to his work in spite of the pain. He had diphtheria in January, 1918, but went back to his farrier work, though the pains were worse than ever. He reported sick in April, 1918, because of debility persisting from the diphtheria. The doctors also put some letters on his sick sheet (? D.A.H.), and discharged him from the army in July, 1919. After a period of light duty as B2, with "something wrong with the heart" (again three letters, he thinks—probably D.A.H.), he took up his trade of cabinet-maker again, and was practically well until twelve months before he came to me, though he had occasional attacks of pain. He then began to find that the pains recurred regularly and that he felt done up by the Wednesday, but he kept at work until Saturday midday, when he went to bed for the week-end. Extra bad attacks would come on every two or three months and he had to go to bed; he then got ease by lying propped up on the right side with his knees up and by hot fannels about the left breast and some brandy. Walking a short distance against the wind would bring on an attack with palpitation and dyspnoea. Although the case was very suggestive of heart strain, there was practically nothing abnormal to be made out in the chest, and the man looked healthy and robust. The Wassermann test was negative. The x-ray photograph showed a heart of the "lying-down" type with the aortic shadow quite well defined, but no dilatation or aneurysm. There was some general peribronchial thickening, especially in the right lung, but otherwise the lungs showed no marked abnormality. The movements of the diaphragm were normal. There was an old-standing adhesion from the left root to the left diaphragm. Pleuritic adhesions do cause pain sometimes when stretched by deep breathing.

The electro-cardiograph record showed impaired conduction from the auricle to the ventricle, but this does not account for the pain.

I meet with this so-called "lying-down heart" occasionally in people who complain, as this man did, of intrathoracic pain or shortness of breath and in whom I can find no objective signs of heart abnormality. It is only revealed by an x-ray plate which I have taken in obscure cases. I cannot say why it should be associated with pain and cardiac debility, or how it can cause pain, if it does cause pain.

FIG. 1.

FIG. 2.

Orthographic tracings: Fig. 1, normal heart; Fig. 2, lying-down heart.

The term "lying-down heart" is used because, as the diagrams show, more of the heart is in contact with the diaphragm than is normal. It is a descriptive and convenient term. I wish to thank my radiological colleague, Dr. J. M. W. Morrison, for the figures which he has drawn from orthographic tracings (Figs. 1 and 2).

#### THORACIC MUSCLE STRAIN.

I will mention briefly as a contrast to the foregoing cases a railway carter who was thought by the railway surgeon to have strained his heart by muscular effort. As a further contrast this carter did not want to claim compensation,

but to be allowed to resume his work. I have mentioned it before (*Clinical Journal*, July 23rd, 1924), but should like to do so briefly again.

G. H., a railway carter, aged 55, was wheeling a hand truck carrying 7 cwt. of goods in October, 1922, when he felt a sharp pain behind the sternum and over the heart but not down the arms. For half an hour he felt short of breath and had to sit down, and attempts to breathe "punished him like a knife." After this he felt practically normal, but reported the incident, according to instructions. He went to work next day, feeling sore before the heart and in the chest, and with a sharp pain now and again when he was lifting heavy weights. He was sent, against his wish, as he wanted to work, to see the company's surgeon, who found nothing wrong, but thinking of the possibility of heart strain advised that the man be sent on to see me. I found systolic blood pressure 150. There was no albumin or sugar, and no arterio-sclerosis; the heart was practically normal, rate 90 standing, no sign of aneurysm. An electro-cardiograph record was taken, but it showed nothing abnormal.

The seat of the pain and its nature and mode of onset certainly suggested the likelihood of strain of the heart from sudden overexertion, but I thought it might be due to strain of a skeletal muscle and of the triangularis sterni. As the man was very anxious to get back to work we accepted this view, but put him back on a lighter job, and he kept perfectly well until he had an attack of encephalitis in February, 1924; from this he recovered.

#### DIFFICULTY IN PROVING HEART STRAIN.

Heart strain is not easy to establish in a court of law because of the difficulty in proving accident. I will briefly relate an instance of this.

A railway porter claimed compensation for strained heart, caused when carrying full milk-cans weighing up to 300 lb. up the station steps with the assistance of another porter, each porter taking hold of one handle of the can. Whilst doing this one morning the projecting flange which strengthens the bottom of the can caught under the overhanging edge of the stairs and pulled the porters up suddenly; this caused a pain over the heart of the claimant and subsequent shortness of breath, which persisted for several months on slight exertion, and kept him in bed most of the time until I saw him on his own behalf. I found that he had some slight enlargement of the heart and symptoms which could have been caused by heart-muscle strain. He was a healthy youth of about 24, though not of robust type; there was no history of venereal disease, but there was some neurasthenic element in the case. I told his lawyer, from past experience, that it would be very difficult to prove "accident"; but I agreed to say what I could on the strain, neurasthenia, and debility theory. It then transpired that the man had been first treated for a feverish cold or influenza, and as his doctor found unexpected cardiac weakness four or five days after the commencement of the illness or influenza he asked the porter if he could have strained his heart in any way. The man then thought of the accident, but had never mentioned it to his fellow porter working with him, or to anyone in the station at the time it occurred, nor did he do so until a week after the doctor had asked if there had been a strain. The railway company's doctor put the condition down to influenza, and on the above evidence produced in court, and heard for the first time, the judge held that an accident had not been proved and that the heart condition was due to influenza, which I think was a proper decision on the evidence.

I really did think that the man, who was not robust, could have strained his heart in the way claimed.

Another case was that of a collier, aged 38, who said that one day in the pit he had lifted a crane weighing 4½ cwt. which had become displaced. He felt short of breath but complained of no pain at the time. A couple of weeks afterwards he had some pains in the joints. He worked for four weeks after lifting the crane and then had to give up because of shortness of breath. I examined him nine weeks after the supposed strain. There was little to be found, only some slight dilatation of the heart with weak and doubled sounds. There was no albumin in the urine and no increase of blood pressure. The man was very short of breath. He was sent to bed for two weeks, and then got up again, feeling no better. He dropped down dead, presumably from heart failure, five weeks after I saw him. No post-mortem examination was held, unfortunately, but the predisposing cause of death was very likely atheromatous coronary arteries.

Here I had no doubt that the man strained his heart in some way lifting the heavy weight, but the court found against him, holding that strain was not proved, and that even if it had taken place could not so badly affect a sound heart, and that there must have been pre-existing heart disease. The case was tried in 1907, before the House of Lords' decision on the aneurysm and the spanner claim, which influenced so greatly the meaning of an accident. I am sorry that I was unable to get a Wassermann test here, for very probably, in one so young, we should have found it positive.

## An Address

ON

# A NEW OUTLOOK ON CANCER:

## IRRITATION AND INFECTION.\*

BY

JAMES YOUNG, D.S.O., M.D., F.R.C.S. Ed.,  
ASSISTANT GYNAECOLOGIST, THE ROYAL INFIRMARY, EDINBURGH.

MORE than three years ago I<sup>1</sup> published an account of an organism obtained from carcinoma, and since then I<sup>2</sup> have described in increasingly more complete detail the morphological characters of this parasite. I have claimed, on the basis of a study of more than sixty cases, to show that this microbe can be obtained almost constantly from cancer. My conclusions have in some quarters met with opposition on two grounds. In the first place, it has been urged that to account for the cancer phenomena it is unnecessary to predicate the existence of a parasite. In the second place, it has been stated that my views are opposed to the established science of bacterial morphology. Within the limits of this paper I propose to deal with these two objections.

Of all the diseases of man cancer has probably the most unique features; it has little direct contact at any point with other morbid processes, and, for that reason, analogy is of small positive help in a search for the cause. The essential fact which marks it off is that, beginning in the proliferation of a small group of cells, it ends, when running its ordinary course, as a myriad host of anarchic cells destroying by direct inroad the healthy surroundings and burrowing often into the springs of life itself. Any class of cells in the body may be seized with this tragic impetus, and, according to their site of origin, so will the cancer differ in structure and, it may be, in deadliness; but in all, no matter what the origin, the same unique features dominate the process, in all we have a plague of riotous cells spreading as a blight without control or cessation.

It is important to stress the essential unity of the cancerous process, especially at the present time, for some observers are so immersed in detail that they have allowed themselves to lose sight of this unity and have accordingly, I believe, fallen into serious error. The differences in detail are seen when malignancy involves structures of different kinds. For example, when originating in squamous epithelium, squamous epithelioma is produced; when in gland acini, glandular cancer; but that these structural differences, which may be considerable in detail, are non-essential in regard to the ultimate nature of cancer is shown by the fact that, in an organ possessing both types of epithelium—for example, the uterus—we may find both types of cancer side by side. So, in the same way, carcinoma and sarcoma may occur together, and the essential similarity between these two such divergent types of "cancer" is further proved by the experimental finding that transplantable cancer may end as transplantable sarcoma, the cancerogenic factor in this case having been transmitted from one class of cell to the other. Considerations of this sort indicate that, where the malignant change is occurring in widely different tissues, the diversity in structure, and it may be in other points as well, cannot be held to justify any diversity in the ultimate nature and cause. The differences are rather local and environmental, and therefore non-essential.

The unique phenomenon of malignancy is not limited to man; it is found throughout the lower animals, and a process of an analogous kind is found also in the vegetable kingdom.

#### CHRONIC IRRITATION.

One of the most important positive facts in regard to the etiology of cancer acquired within recent years concerns the role played by chronic irritation. The experimental production of cancer in animals by the exposure of the skin to chemical irritants, of which there are now several, has lifted a long-established clinical observation into the realm of proved laboratory fact. It can now be claimed with

\* Delivered in opening a discussion on cancer at the Liverpool Medical Institution, December 11th, 1924.

certainly that cancer can be induced by factors which vary as greatly in their nature as do tar, soot, arsenic,  $\alpha$  rays, heat, etc. By some these isolated and distinct irritant influences have been adduced as necessarily so many direct "causes" of this unique process. To many who have followed the specious arguments which have sometimes been advanced in support of this extraordinary claim it must come as a surprise that even distinguished observers may be negligent of the warning lessons of medical history. Sixty years ago to claim that the specific disease, phthisis of the lungs, had a multiplicity of direct causes was in keeping with the knowledge of the period. Thus it was believed that the inflammation of a bronchitis, the irritation of the inhaled fragments of stone with which the mason worked, etc., were each one a direct "cause" of pulmonary phthisis, and that there were many other causes as well—for example, heredity, unhealthy environment, etc. Time has shown that the greatly differing direct irritants and the other indirect agencies operate in one common way—by increasing cell and tissue susceptibility to the one common factor, the *tubercle bacillus*. In many other cases the history of medical progress has shown that, where several causes have been advanced to account for a disease, these have proved to be nothing more than factors preceding, and predisposing to, the single common agent.

#### NATURE OF THE CANCEROGENIC FACTORS.

There are two facts which stand out distinctly in those cases where chronic irritation plays an antecedent part. (1) The regions so affected are typically covered by an adult resting epithelium—for example, lip, cheek, bowel, cervix uteri, etc. (2) The irritant influence typically has to operate for a long period, it may be months or even years, before the appearance of the cancerous change.

However we attempt to assess the influence of irritation we must admit that the special cellular alteration culminating in cancer must be a common effect of all the different materials and influences concerned—for example, tar, soot, arsenic, heat,  $\alpha$  rays, etc. Cancer implies such a unique reversal of cellular activity that it is impossible to escape this conclusion. As I have pointed out, it must also be evident that the differences in structure in the tumours produced when irritants act on different classes of cells must be due to the original structural difference in the tissue involved and not to any difference in cause. It must be clear that the same irritant operating on the skin will tend to produce squamous epithelioma, whilst on a gland surface it will tend to produce a cancer derived from the gland cells, and so on. It would seem unnecessary to stress such an obvious fact were it not that some observers have inferred that in cancer we have a jumbled congeries of morbid conditions. Read aright, the confusing array of "causes" comprise so many different ways in which the common cellular upheaval is induced.

Even a superficial study of this cell upheaval proves that it consists of an alteration of the affected tissue in such a manner that cells which were previously well behaved and orderly and stable have acquired the power of ready and continuous proliferation. In a healthy epithelium there are always cells which can proliferate to repair damage, but under normal conditions such dividing cells constantly tend to differentiate into stable resting elements. Where the damage is long-standing there is gradually acquired an increasing impetus to reproduction and a diminishing impetus to differentiate. The one property is exaggerated at the expense of the other.

By some observers it is believed that the cancerous tendency is the direct outcome of the irritative process without the operation of any other factor. This view implies that where the tissue is damaged for a sufficiently long time in a certain way the cells eventually gather such a momentum of proliferation that this goes on in an unending and destructive sequence. Opposed to this view is that of those workers who, while agreeing that irritation probably operates by unblocking the reproductive faculties of the cell, suggest that the real immediate stimulus to a cancerous proliferation consists of a new and different stimulus added to the susceptible cell. So long as the epithelium consists of healthy stable cells the immediate

cancerogenic factor is inoperative. Let this stability be undermined in any one of a variety of ways and the addition of the immediate factor launches the cells on their disastrous career.

That there are two such factors, each the complement of the other and each equally essential—namely, an antecedent cell susceptibility and an immediate agent—is indicated by a study of those cases of cancer where chronic irritation does not play the part that is so obvious where an adult epithelium is concerned. In chorion-epithelioma the cancerous change typically overtakes the chorionic cells within a short time of their being stranded in the uterus; there is not the delay which characterizes a cancer, for example, of the cervix uteri, where the antecedent chronic irritative change may be in operation for years.

This distinctive difference in the time onset of the chorionic cancer is clearly to be correlated with the fact that in the chorion we are dealing from the beginning with susceptible cells—cells, in other words, already naturally endowed with marked reproductive powers. This state is natural to the cells, but obviously cannot of itself drive them to cancer without the existence of some other factor. Loose thinking is responsible for an attitude which sees an ample explanation in looking upon chorion-epithelioma as dependent upon a cell which has become excessively embryonic. This attitude, which, I believe, has done more than any other single error to obscure the real issue, fails to recognize that between the embryonic cell and the cancer cell there are differences not of degree but of kind. These differences are fundamental, and it is impossible to evade the conclusion that chorionic cancer is due to the addition of some drastically new factor to a cell already by nature able to respond. In somewhat the same way the ovum is an embryonic cell, and it becomes launched on its career of segmentation because its "proliferability" allows of a very special response when the new and necessary extrinsic factor is added to it.

There are other considerations which suggest that in chronic irritation there is only one of the factors concerned in the cancer process. For example, it is well known that not all surfaces exposed to chronic irritation become cancerous; and, moreover, the cancer when it does appear develops as a wholly new phenomenon, often many months or years after the damaging process has been in full swing. The conditions suggest that the chronic irritation is one thing, the cancer another thing, and the abrupt leap from one to the other implies the accession of some new factor.

**Factors a and b.**—The essential problem revealed by the study of cancer as it develops, on the one hand, in an adult epithelium rendered primitive by irritation, and, on the other hand, in an epithelium primitive by nature, may be depicted in the following formula, where the two cancerogenic factors are represented by a and b:

Adult epithelium + a + b = cancer.

Primitive epithelium + b = cancer.

A conception of this sort at once removes the confusion with which the irritation factor has been surrounded. It relegates it to its proper place, and it moreover disposes at the same time of much of the loose argument which has been advanced against the parasitic hypothesis.

#### TWO FACTORS IN PARASITIC PLANT TUMOURS.

In plant tumours we find an interesting analogy with the dual factors operating in cancer. In the plant this dual phenomenon—cell susceptibility and immediate cause (parasite)—is very clearly represented. The immediate and necessary agent is the parasite, but this is potent only when it operates on a cell capable of, or in the act of, continued proliferation. It thus happens that the tumours develop in areas where the cells are young and primitive—for example, in warty disease in potatoes, where the tumour begins at the "eye." So in crown gall, a plant neoplasm caused by the *Bacillus tumefaciens*, the tumour growth originates in tissue which is primitive and capable of further growth, and not in resting adult tissue. Erwin Smith's investigations have shown the many and intimate ways in which crown gall resembles cancer in animals. The growth can be grafted on to other plants of the same species. It can be cut out, but it will recur if all the

tumour has not been removed. It destroys both by compression and by infiltration, and the latter process may spread into healthy tissues for a considerable distance from the original focus. Ordinarily the growth consists, as in cancer, of actively dividing cells with little tendency to differentiate. On the other hand, where multipotent cells are affected a true differentiation from tumour issue into leafy organs may take place, culminating in a malignant plant embryoma in essentials comparable to the malign embryomata of animals. As Erwin Smith reminds us, Jensen was so much impressed by these striking resemblances between crown-gall tumours and his mouse cancer that he considered them of much service in throwing light on the etiology of neoplasms, especially as, like cancer, they could not be considered as due to the operation of micro-organisms! A final and significant fact with regard to crown gall is that, as Erwin Smith points out, it tends to develop on irritated places. The irritation must clearly operate either by producing an abrasion in the tougher tissue by which the parasite can gain access to the primitive cells or by driving the mature resting elements back to the primitive state.

The conditions obtaining in these plant neoplasms bring out in a very clear light that, whilst the factor of cell susceptibility is a necessary antecedent, the *b* factor (parasite) alone can stir the cells into a malignant overgrowth.

#### HEREDITY IN CANCER.

Amongst some of the other facts on the general etiology of cancer which have been accumulated during recent years are those bearing on the hereditary basis of malignant disease. By an extensive series of experiments Maud Slye<sup>4</sup> has shown, apparently conclusively, that in the mouse there exist characters of individual resistance to and of susceptibility to the development of spontaneous cancer. These factors of resistance or susceptibility have an hereditary value, and, by selection, this observer has been able, on the one hand, to breed a race of mice insusceptible to cancer, whilst, on the other hand, she has bred a race every individual of which over a number of generations develops cancer, sarcoma, or pseudo-leukaemia. The latter condition Slye considers to be a form of malignant disease.

These findings are striking, and have been advanced by Slye as an argument against the infective nature of malignant disease. Such an argument would be logical only if it can be shown that susceptibility to infection, which exhibits great individual variation in man and animals, were a phenomenon with no dependence on heredity. So far is this from being established that some writers actually profess to have demonstrated that resistance to and susceptibility to infection are transmissible factors. Webster<sup>5</sup> has shown this recently in mice with regard to resistance to infection with organisms of the typhoidal group.

Plant pathology provides again a suggestive analogy along these lines, for in the case of some of the parasitic tumours the heredity element may be prominent. In warty disease in potatoes, for example, it is common knowledge that the tendency to infection with the tumour-producing parasite varies greatly in different strains of potato. The recognition of this fact has led to the almost complete stamping out of what threatened to be a severe scourge by the success which has attended the efforts of horticulturists to breed immune stocks.

A general consideration of the phenomena underlying the factor *a*, the antecedent susceptibility of the cell to neoplasia, thus suggests that, as in other diseases, it is a compound of several factors, amongst which the operations of both heredity and irritation may be apparent.

An analysis of the data carried out along the lines which I have indicated leads to conclusions in no way opposed to an organismal conception of cancer. If the argument be sound which impels us to predicate the necessary existence of another and a more immediate factor in those cases where chronic irritation plays an obvious antecedent role, it is clear that a strong presumptive claim for a cancer parasite is established.

Another consideration in this connexion is that underlying the immediate cancer-producing agent there are two

mutually dependent facts. First, it must be clear that, however we interpret this factor, any indirect agency can only operate by adding to the cell something by virtue of which it is lashed into its unduo reproductive activity. Secondly, it is clear that this new factor, once within the cell, is perpetuated and multiplied without ceasing, for only by its continued presence can the unending cell divisions and destructive growth be explained. It cannot be supposed that there are two separate factors, for this implies that the factor which stirred the first cells to a cancerous proliferation is different from that by which the later divisions are induced. The factor added from without and the factor which is then multiplied from within must be one and the same. Unless we can conceive of a motive power received *de novo* by the cell and then perpetuated by the cell, we are driven back to a living parasite as the sole possible explanation.

Despite the suggestive evidence supplied by the existence of so-called cancer houses and cancer eages, cancer has no obvious infective characters. This of itself is, of course, no proof of its non-organismal origin, as some diseases of definite micro-organismal nature may lack infectiveness in the ordinary sense. Just as there are all degrees in this character of infectiveness amongst diseases which owe their immediate production to a parasite, so cancer has some links with diseases whose general clinical and pathological associations presuppose an infective basis. I have said that cancer has unique features and that analogy is of little help in a search for the cause. If, however, we include within the scope of the cancerous process all the conditions with the same manifestations of a malignant cell proliferation—for example, chicken sarcoma, infective sarcoma of dogs, and the leukaemias—we find very definite support for the parasitic view. In all these conditions there is strong evidence of an infective basis, and the "leukaemic" state is especially interesting and suggestive, because in it are embraced all grades between lesions with obvious infective traits and lesions which are indistinguishable from malignant growths (lymphosarcoma).

#### THE CANCER PARASITE.

This I have described fully elsewhere, and in this place I can refer only to the general features of the organism and to the extensive support which my views on these characters obtain from bacteriological literature. I have shown that the microbe has a complex morphology, appearing in a variety of forms, each of familiar type and each capable of leading an independent life: hyphae, yeast, coccus, and bacillus. In addition I have described an amorphous phase or "plasm." I have urged that the failure to recognize this varying morphology has vitiated the problem from the outset, and I have claimed to show that an understanding of the alternative forms assumed by the organism under different conditions of life serves to unlock the secret of cancer, for the phase living symbiotically within the cell is wholly different from that found growing ordinarily in the test tube.

In support of these views I now have a mass of evidence so great that it is almost impossible to handle. Added to this, the literature proves that a large and increasing number of bacteriologists entertain views on general bacterial morphology similar to those for which I stand. Any close student of this literature cannot fail to be impressed with the tendency amongst practically all investigators on morphology to identify the bacteria with the fungi, and to look upon each form (coccus, bacillus, etc.) as merely one of several shapes in which the same organism can appear and in each of which it can grow true to type. The evidence, indeed, is so great that it must have been apparent to many that the very foundations of bacterial classification are tottering.

Many investigators have described cocal, bacillary, blastomyceto, and hyphal phases as occurring in the life story of the same organism, and, within recent years, work based upon the employment of single-celled cultures has removed the last shred of criticism that the innumerable instances of variability can be discarded summarily as "contamination" (Mellon,<sup>6</sup> Hort,<sup>7</sup> de Negri,<sup>8</sup> etc.). The fact, established by many workers, that each such variant

can propagate itself true to type in a vigorous normal fashion, disposes also of the objection comprised under the term "involution," which in such circumstances is robbed of all meaning.

The present position is rendered all the more confusing by the demonstration that not only is bacterial form unreliable for purposes of classification, but that the very factors which, in the past, have been considered as belonging to the most delicate of the means of distinction (for example, Gram's stain and the serological reactions) may in the same organism differ within as large a range as the morphology. These variations may imply nothing more than an index of the physico-chemical alterations which an organism exhibits during its changing morphology.

#### THE AMORPHOUS PHASE.

From the beginning of my research I have urged that it is this amorphous and often unsustainable substance that we have to look for the secret of the cancerous process. Elsewhere I have given evidence that, in this phase, the organism lives in symbiosis with the cancer cell, and the flora which quickly appears in a piece of incubating cancer tissue is derived from the rapid increase and the organization of this material under conditions of laboratory environment, which differ wholly from those obtaining in the living body. From this "plasm" any or all of the various forms can be derived. It is thus totipotent. On occasions I have seen it becoming organized simultaneously into yeast, coccus, bacillus, and filament. The details of this phenomenon I have described fully elsewhere.

This amorphous alternation in the mode of life of bacteria has been described by many workers under a variety of names. It has been noted in practically all known bacteria. Some investigators have dismissed it as an inert matter formed by a crumbling of living cells. By many others, however, it has been recognized as a homogeneous, often hyaline and highly refractile living substance, in which the organizing vegetative forms are laid down as granules, which subsequently enlarge into the mature elements. As Löhnis<sup>9</sup> has pointed out in his exhaustive summary of the literature, it has been described as such from early days down to the present time (Ray Lankester, Klebs, Koch, Haberkorn, Malassez and Vignal, Pernet, Rosenbach, Maher, Herzog, Almqvist, Kellermann and Scales, Mellon, Löhnis and Smith, de Negri, etc.). The extent and unanimity of the findings of such a large body of independent workers leave no doubt of the reality of this alternative mode of bacterial life. Whilst this is so, the indefiniteness of its appearance and, in some stages, its complete absence of structure have made it a phenomenon of extreme elusiveness. For these reasons, apparently, the early investigators were deterred from devoting to it the attention which more recent research shows it to warrant. For it must be clear that the recognition of this class of structure brings into the science of bacteriology a fact of very great practical importance, as well as one of considerable academic interest. A most comprehensive study of this form has, within recent years, been carried out by Löhnis, who rightly insists that in it is to be found the means of co-ordinating much in morphology that is at present in a state of chaos.

In justice to my own work, and incidentally as an argument in support of the general facts surrounding this plasm phase, I must state that during the first period of my research I was in ignorance of the work of my predecessors, and my recognition of this phase came independently as the result of a search for the source of bacterial forms, which, during the early stages of incubation of a cancerous growth, could always be seen to appear first as very minute elements, which were often gathered into bundles scattered throughout the tissue. In my most recent paper I have shown by means of photomicrographs that the forerunner of these organized elements consists of an amorphous slime which exudes from the cancer cells and appears first as globules or as filaments, which ordinarily are very unstable and persist for only a few hours. [By means of lantern slides Dr. Young showed the plasm emerging from the cells as pale rods, filaments, or globules of greatly differing size. The alternative ways in which the plasm became organized were shown.]

As I have pointed out, the essential link in the chain of bacterial morphology is the amorphous phase. Without it an understanding of the phenomena is impossible, for, after organization, the different individual forms which arise from this phase may each pursue an independent morphological career, growing true to type as yeast, coccus, bacillus, etc., when the common origins are quickly lost. It is sometimes urged that this conception of morphology is unlikely on biological grounds. The multipotential property of the bacterial plasm is, however, surely no more extravagant a conception than the multipotency of the germ plasm of higher organisms. In both instances, with development, an unfolding into differentiated cells is found, and in both the individual cells tend to grow true to type. In the higher organisms, as recent research has shown, the true to type growth may, like that of bacterial cells, even continue when the cells are separated from the body and placed in the test tube in a suitable medium. The analogy, it is true, must not be overstrained, for in the case of the higher organisms the unfolding of cell types is by a ladder-like sequence, whilst the bacterial plasm may differentiate directly and, as it were, on a flat plane into the variegated forms. Moreover, with the bacteria, although differentiation may apparently be complete—so complete indeed as to have given rise to the whole superstructure of monomorphic bacteriology—the careful studies of many observers have shown that, with a suitable environment, even the most stable elements can quickly retrace the whole morphological compass of the race. Each element has, as it were, the totipotency of a germ plasm. Again it may be urged, however, that amongst the more primitive of higher organisms a similar totipotency may be present, and that we are on safe biological grounds in insisting that any differences in these respects are of degree and not of kind, and are satisfactorily accounted for by the evolutionary simplicity of the bacteria.

To those with imagination and courage the fresh fields opened out by these new data furnish an unbounded opportunity for research. I cannot do more than touch on one or two topics that invite a vigorous attack. An amorphous phase of the tubercle bacillus, for example, was described by Klebs,<sup>10</sup> Malassez and Vignal,<sup>11</sup> and others many years ago. Such findings have naturally been submerged during the era of monomorphic bacteriology. They must, however, soon be revived by the discovery of several recent writers—for example, Valtis,<sup>12</sup> Vannucci,<sup>13</sup> and others—that the filtrates of tuberculous tissue are capable of producing on injection typical tuberculous lesions in animals, although from such filtrates no tubercle bacilli can be grown. So, also, to those who are conscious of the drift of recent bacteriological discovery, it must seem not unlikely that the chaos of morphological forms associated with influenza will find its solution in the new and broadened outlook.

It is apparent that with a substantiation of the views which are rapidly gaining ground in bacteriology must come a strong confirmation of my conception of the cancer parasite. It must also be equally apparent that some at least of the organismal forms previously obtained from cancer by different workers are in reality isolated alternative phases in the same cancer organism. This view I have urged from the beginning of my research since I discovered that within the morphological range of my organism were elements not to be distinguished from the yeasts of Plimmer, San Felice, etc., the coccus of Döyen, the filtrable micrococcus of Nuzum, etc. The nearest anticipation of my own work I believe to be that of Monsarrat,<sup>14</sup> who in 1903 described several bacterial forms obtained from cancer which correspond to some of the phases included in the life story of the organism described by me. Monsarrat, at the stage which his investigation reached, did not claim any definite significance for his organism. These previous observations all suffered, I believe, from the failure to discover the key to the problem, which is to be found in the "plasm" phase—the phase, as we have seen, that constitutes the essential link in the cycle of the organism, and is at the same time the secret of its parasitic mode of life.

I have pointed out that many recent observations prove that the methods usually employed for the differentiation of species are ill adapted for the purpose for which they are devised. This applies not only to morphological appear-

ances and staining characters, but also to serological and sugar fermentation reactions. In previous papers I have shown that different phases of my organism differ from one another widely, not only in morphology, but also in staining and sugar reactions. This aspect of the question, however, is in the meantime relatively unimportant, and is of little help so long as morphology is in its present unsatisfactory state. It cannot do more than multiply distinctions which are non-essential if the new lines of research are well founded.

#### CONCLUSIONS.

1. There are two completely independent factors underlying the change of a normal cell into a cancer cell. The first is an antecedent cell susceptibility. The other is the immediate cancerogenic factor. Analysis shows the antecedent cell susceptibility to be the capacity for continued proliferation in the body, and, when possessed naturally by the cells ("embryonic"), allows of a development of cancer when the immediate cancerogenic factor is added. In the case of a mature epithelium this cell susceptibility is acquired often as the result of chronic irritation. When the cancerogenic factor is now added cancer is possible.

2. In plant tumours this dual phenomenon—cell susceptibility and immediate agent (parasite)—is well seen. It explains why in warty disease of potatoes, crown gall, etc., infection by the parasite produces neoplasia in the healthy plant only when cells of a primitive kind are affected. Irritation of a mature surface of the plant may, however, make it susceptible to neoplasia after infection.

3. An organism with a complex life story has been obtained almost constantly from cancer. It possesses yeast, coccid, bacillary, and amorphous phases, and each of these can grow true to type and live a wholly independent life. Evidence has been given that the parasite lives in symbiosis with the cancer cell in the amorphous phase, and it is from this that all the other phases are derived during incubation of a cancerous growth. The discovery of this phase, it is claimed, provides the key to the cancer phenomenon, as also the key to the morphological variants.

4. The morphological features of this parasite resemble the life story described by many writers for other classes of pathogenic organisms. There is now strong evidence to support the view that a similar morphological variability is common to all bacteria and that bacterial classification is in need of revision.

5. The parasite belongs to familiar bacteria which are widespread in nature, and the ease with which cancer can be induced experimentally in animals by chronic irritation suggests that tissue susceptibility wherever found implies the immediate risk of infection by a ubiquitous organism.

The free and universal exposure of man and animals to infection, combined with the (relatively) small proportion of the total which develop cancer, suggests the all-importance of cell susceptibility, and corresponds to the laboratory difficulties attendant on an attempt to produce cancer experimentally by the injection of the organism. In previous papers I have shown that a marked proliferation of primitive tissues can sometimes be induced in animals by the experimental injection of the cancer organism. This proliferation may resemble an ordinary infective process, whilst in an advanced case it simulates a progressive lymphoma or pseudo-leukaemia.

The investigations described in this paper were carried out at the Royal College of Physicians Laboratory, Edinburgh.

## DIAGNOSIS AND PROGNOSIS IN CHRONIC RENAL DISEASE:

THE RANGE OF UREA CONCENTRATION OR RANGE OF FUNCTION TEST.

BY

EDWIN G. B. CALVERT, M.D., M.R.C.P.,  
ASSISTANT TO THE DIRECTOR, MEDICAL CLINICAL UNIT, ST. MARY'S HOSPITAL.

THE purpose of this paper is to describe the above test, and also briefly to comment on other methods of investigating chronic renal disease. During a study covering three years extensive trial has been made of: (1) The urea concentration test (Macleod). (2) Estimation of urea or non-protein nitrogen in the blood; the uric acid, creatinine, inorganic phosphorus, and diastase contents of the blood have also been determined in many instances. (3) Diastase value of the urine. (4) The various dyo tests. (5) Water and salt excretion tests. (6) The variations in reaction of the urine.

Like others, I have not infrequently been surprised by the degree of destruction of kidney tissue found *post mortem* in some cases in which the tests failed to indicate inefficiency, or by the disparity between the amount of damage and the calculated impairment of function. Actually, certain workers have shown by experiment that as much as three-quarters of the total kidney substance may be removed before any abnormal accumulation of urea occurs in the blood. Apparently positive results are only obtained when the reserve power of the kidneys is reduced to a certain low level or when failure of compensation sets in. More sensitive methods are required, and it is in hope of stimulating, however slightly, further research that I venture to record the following notes.

#### The Urea Concentration Test (Macleod<sup>1</sup>).

In carrying out this test in "normal" individuals one is impressed by the wide range of results. Thus, in one series the maximum concentration varied from 1.8 to 5 per cent.—usually found in the second, sometimes in the third, and occasionally in the fourth hour-period. Inquiry proved that, as a rule, the low figures were obtained in persons whose twenty-four hour urine was considerably greater than the average in volume (and incidentally less in concentration) and the high figures in those whose volume of urine was less than the average, the same amount of fluid having been taken in each instance. The above findings, therefore, are not altogether extraordinary, and seem merely to reiterate the fact that marked variations occur in the response of normal people to other diuretics, such as water, tea, and prolonged exposure to cold.

When the "resting level" of urea in the urine (that is, the percentage prior to the test) is taken into account we gain a better idea of the value of Macleod's figure. For example, a result of 3 per cent. which is derived from a resting level of 0.9 per cent. indicates a greater degree of renal (perhaps better termed cardio-vascular-renal) efficiency than the same concentration derived from a level of 2.3 per cent.; or again, 1.8/1.0 per cent. means better function than 1.8/1.5 per cent.

Quite a number of seemingly normal cases have been encountered in which the test results did not exceed 1.6 or 1.7 per cent.; in all of these, however, the volumes of four-hourly specimens somewhat exceeded (by 10 to 30 c.cm.) the prescribed limit, the urea having had prolonged diuretic effects. But when the test was applied over the hours most conducive to concentration—the period of sleep—percentages of 2.2 to 2.8 were obtained; the "resting levels" (7 to 9 a.m.) stood at 0.9 per cent. approximately. It is now clear that the lower the latter value the more does the maximum concentration indicate efficiency, and also that in employing tests of this nature the fullest attention must be paid to the ability of the kidneys to excrete water.

#### The Water Secretion Test.

This test takes note of the proportion of water passed over the day and night hours, and also of the variation in the rate of secretion during the former. In the normal

the night volume is roughly about one-fifth that of the day, and during the latter period the rate of secretion and the specific gravity of specimens fluctuate greatly, depending on the amount of fluid taken. In advanced chronic renal disease "fixation" of volume and specific gravity is noticed; the night urine is decidedly increased and may equal or even exceed that for the daytime, thus showing that the reserve power of the kidneys has been lowered.

The foregoing tests are an expression of the concentration-dilution power of the kidneys. The healthy kidney can quickly adapt itself to alterations in the amount of fluid supplied to the circulating blood—any disturbance of water and molecular equilibrium is rapidly restored. In terms of Cushing's theory,<sup>2</sup> excess of water is removed by increased filtration and diminished absorption, while deficit is compensated for by an opposite process. In the diseased condition both the total filtering power and the total absorption power are defective, and since the kidneys have the task of eliminating a certain amount of waste products daily their range of action in excreting urine of high and low concentration must be less than normal. Clinically we recognize two widely different types of chronic renal disease; a mixed type falls between the two extremes. On the one hand we have chronic interstitial (or azotaemic) nephritis, on the other chronic parenchymatous (or hydraemic) nephritis. In the former variety Maclean's test usually indicates inefficiency, but in the latter it yields a normal figure; that is to say, in one case the test is of value, in the other it fails.

From what has already been said of the concentration and dilution powers of normal and abnormal kidneys, it will be agreed that not only should the maximum concentration be determined but also the "minimum." A test of this sort will reveal defect of function in both forms of the disease and in the mixed variety. In hydraemic nephritis the failure is to diuresis, in the azotaemic to concentration. The capacity for concentration is best examined over the period of sleep, when absorption of water from the tubules is naturally at an advantage and normally most marked, while the ability to form a dilute urine is best determined during the waking hours, when the kidneys are most sensitive to diuretics. Concentration depends not only on the state of the glomerulus and the tubule, but also on that of the heart's action and blood pressure, and as the same may be said of diuresis we see that the values obtained for the two processes enhance one another. The range of function, as denoted by such figures, is a statement of relativity; the minimum value forms a basis from which to judge the maximum, and vice versa.

#### Range of Urea Concentration (R.U.C.) or Range of Function Test.

No originality is claimed for this test; it is merely an adaptation of the above methods of determining renal function. I have used it in some 300 cases of renal disease during the past three years, comparing it with other methods and correlating the results with the clinical, and, when possible, the *post-mortem* findings. It has proved most valuable. The details are:

The taking of fluid during the five to six hours preceding the test is forbidden. Thus little fluid is taken at tea-time (5 o'clock), and none with the evening meal (7 to 8 o'clock). At, say, 10 p.m. the patient (an adult) drinks the following 3-ounce dose: urea 5iv, tr. aurant. ʒss, ag. ad ʒijj. An hour later (11 p.m.) the bladder is emptied and the urine discarded. The patient is then kept warm in bed and encouraged to sleep. All the urine is collected from 11 p.m. to 7 a.m., the bladder being completely emptied at the latter hour; a sample of this is known as "Specimen A." At 7 a.m. plenty of fluid is given. Thos between 7 and 7.45 a.m. the patient sips two large cups of weak tea, containing little or no sugar, followed by a pint of water—that is, about 30 oz. in all. The urine is collected from 7 to 9 a.m.; a sample of this is known as "Specimen B." "A" gives the maximum concentration of urea, "B" the minimum; the exposure of dressing aids diuresis in "B." That the ingestion of such large amounts of fluid, especially when taken slowly, has no detrimental effect has been pointed out by Orr and Innes.<sup>3</sup> On the contrary, the results seem to be beneficial—possibly owing to the elimination of pressor substances, etc.; of course, where the patient is waterlogged the giving of so much fluid is inadvisable. The collections may be made from 10 or 11 p.m. to 6 a.m. and from 6 to 8 a.m., if found more convenient. The urine is discarded up to one hour after the giving of the dose of urea in order to allow any diuretic effects to pass off.

It was essential to ascertain the variation of concentration throughout the night period, so as to ensure that a high concentration obtained during the earlier hours was not being lowered by subsequent excretion of more dilute urine. Consequently twenty individuals with "normal" and fifteen with "abnormal" kidneys were tested by examining specimens of urine collected every two or three hours. The following are typical examples:

	Concentration of Urea in Urine.	
	Normal.	Chronic Interstitial Nephritis (10 cases).
Urea given at 10 p.m.		
11 p.m. to 1 a.m. ... ..	3.35 per cent.	1.60 per cent.
1 a.m. to 3 a.m. ... ..	3.40 ..	1.58 ..
3 a.m. to 5 a.m. ... ..	3.35 ..	1.52 ..
5 a.m. to 7 a.m. ... ..	3.03 ..	1.53 ..

The concentration is well maintained throughout the night, and there is therefore no need to disturb the patient's rest by endeavouring to obtain a specimen over the early hours of the test. In a few normal persons the percentage falls a little in the latter specimens, but the error introduced is negligible; in the cases of renal disease no fall was noticed. The percentages obtained in this way are higher than those given by Maclean's method. It is instructive to compare the results obtained over the "A" and "B" periods in the normal, and in cases of chronic renal disease, when (1) no urea and no water were given (at the beginning of "A" and "B" respectively); (2) urea and no water given; (3) no urea but water given; (4) urea and water given. The following results are typical (the figures represent percentages):

Group.		Normal.	Marked Chronic Interstitial Nephritis.	Marked Chronic (or rather "Subacute") Parenchymatous Nephritis.
(1) No urea and no water	A B	2.20 1.20	1.24 1.24	2.52 2.40
(2) Urea and no water	A B	3.40 1.40	1.33 1.25	2.60 2.50
(3) No urea, but water	A B	2.23 0.33	1.23 1.05	2.50 2.35
(4) Urea and water (that is, the R.U.C. test)	A B	3.82 0.40	1.32 1.12	2.60 2.40

The table shows the normal swing in concentration from night to morning urine (Group 1), and illustrates how the range of urea concentration test (Group 4) is designed to exaggerate this phenomenon. Often the swing in the "normal" is much greater than here represented—for example, "A" may be 5.5 per cent., and "B" only 0.3 per cent.; this is taken to indicate a greater degree of efficiency of the cardio-vascular-renal system. Further, it has been noticed that in some cases the degree of range is due mainly to the rise of concentration, in others to the fall, the "resting levels" being taken as a basis.

Occasionally one encounters a person oversensitive to diuretics and ordinarily passing a large-volume urine, but otherwise apparently normal, or a person suspected of having renal disease in whom results such as the following are obtained: maximum concentration 1.6 per cent.; minimum concentration 0.3 per cent. In one patient passing 5 pints of urine daily and considered to be suffering from mild diabetes insipidus the maximum figure was 1.3 per cent. and the minimum 0.2 per cent.; the amount of fluid given in this test was 2 pints. The range of function in these cases differentiates them from those of chronic interstitial nephritis having the same maximal concentrations; the range in the latter is markedly less, and, in the worst cases, may be nil. In subacute parenchymatous (that is,

hydraemic) nephritis the range may be equally limited, but it is set at a higher level with the maximum, and indeed one might say the minimum, figure practically always above 2 per cent. If in this condition the blood pressure rises and the heart hypertrophies sufficiently to counterbalance the defect of the kidneys by increased circulation and filtration in the glomeruli, the oedema subsides and the kidneys may be said to have passed into the stage of contraction. The range of function may still show the same limitation as before, or it may be increased or diminished, but the maximum value is almost certain to be lowered. It is my experience that, taken conjointly, the lower the maximum concentration and the more restricted the range, the worse the prognosis.

#### Correlation of the Test Results and Various Pathological Findings.

The following cases will serve as illustrations.

##### CASE I.

T. C., aged 48, came under observation two years ago. Very pronounced subacute parenchymatous nephritis; oedema extreme. Urine: a few ounces daily, 0.8 per cent. albumin, 0.07 per cent. chlorides (as NaCl). Heart seemed to be normal. Blood pressure 138/90 (systolic and diastolic respectively). Blood urea normal. Fundus oculi normal. Range of urea concentration (R.U.C.): "A" = 3.8 per cent., "B" = 3.6 per cent. After eight weeks' treatment with large doses of urea and an occasional course of digitalis the oedema had completely disappeared and the patient was feeling remarkably well. On examination:—Urine: volume 60 oz., 0.2 per cent. albumin, 0.53 per cent. NaCl. Left ventricle hypertrophied; apex beat  $1\frac{1}{2}$  in. out. Blood pressure 160/102. Blood urea 0.077 per cent. R.U.C., "A" = 1.9 per cent., "B" = 1.5 per cent.

As observed by these tests fortnightly, the condition ran an even course, and after eight months the findings were: general condition still good, moderate anaemia, no oedema. Heart: apex beat now 1 in. out. Blood pressure 176/110. Blood urea = 0.076 per cent. No eye changes. Urine: 60-70 oz., 0.1 per cent. albumin, R.U.C. = 1.7/1.4.

I saw him again two months later. He had lost much weight; his appetite was poor, sleep fitful, irritable, moderate dyspnoea, occasional headaches. Heart as before. Blood pressure 179/120. Blood urea 0.101 per cent. Urine: 80-90 oz., albumin less. No eye changes. R.U.C. = 1.4/1.2. Death occurred one month later from uraemia, and at autopsy contracted, greyish, granular kidneys were found.

##### CASE II.

G. N., aged 45; admitted into hospital twenty months ago complaining of headaches, sleeplessness, nocturnal polyuria, and dyspepsia. Rheumatic fever in childhood. Urine: Merest trace of albumin, specific gravity 1005, 70-80 oz., about 9 g. chlorides (as NaCl) daily. Heart: Left ventricle hypertrophied; apex beat 1 in. out; no bruits; action regular. Blood pressure 198/120. Blood urea 0.107 per cent. No eye changes. R.U.C. = 1.65/1.3. During his six weeks' stay in hospital he was much relieved subjectively. Five months later he returned in a worse condition; the heart frequently missed a beat. Blood pressure 200/139. Blood urea 0.162 per cent. R.U.C. = 1.5/1.4. He got gradually worse, and in three weeks' time examination showed: Blood pressure 181/136. Blood urea 0.160 per cent. Urine about 50 oz. R.U.C. = 1.5/1.45. The heart was failing rapidly. At autopsy, a few days later, kidneys typical of so-called "primary" chronic interstitial nephritis were found.

##### CASE III.

Mrs. E. D., a patient still under supervision of the Medical Unit at St. Mary's Hospital. Admitted December 19th, 1923, suffering with marked oedema of legs, trunk, and arms, and there was much secondary anaemia. The illness was due to chronic interstitial nephritis; no attributable cause. On admission:—Urine: 40 in. Heart normal. Blood pressure 120/80. On account of the oedema, blood could not be obtained for urea estimation. Urine: 8 to 15 oz.; 1.2 to 1.5 per cent. albumin; a great number of granular, hyaline granular, and fatty casts present; no blood cells found; chlorides (as NaCl) 0.2 per cent. R.U.C. = 1.2/1.2.

After treatment with urea and digitalis the oedema began to subside until on February 13th, 1924: Girth 35 in. Heart as before. Blood pressure 108/82. Blood urea 0.046 per cent. Urine: 30 to 50 oz.; 1.8 per cent. albumin; only no blood cells; chlorides 0.3 per cent. the oedema was still very marked, this for the future and at once clearly of the kidneys from that in Case I, which until now it closely resembled.

On March 1st oedema had completely disappeared. On examination on March 3rd, 1924: Girth 27 in. Heart normal in size and action. Blood pressure 110/75. Eyes normal. Urine: 50-60 oz.; 0.7 per cent. albumin; an occasional cast; no blood cells. R.U.C. = 4.45/2.7. When I saw her last, a short time ago, she was in excellent health; findings unaltered. I think that these results, especially the condition of the heart and blood pressure and the R.U.C., show that the kidneys have recovered a great deal of their normal function.

The destruction of the renal elements indicated in the above cases, and found in many others post mortem, is in conformity with the concentration values obtained.

#### Hyperpiesia.

Since hyperpiesia is so closely allied clinically to chronic interstitial nephritis, one may, for purposes of differential diagnosis, cite the following case as representative of a group of the former I have investigated.

##### CASE IV.

H. W., aged 56, suffering from violent headaches, recent failure of eyesight, general debility, and occasional marked nocturnal dyspnoea. Heart: Left ventricle much hypertrophied; no evidence of valvular lesion. Arteries thickened but not tortuous. Blood pressure 230/134. Blood urea 0.051 per cent. Retinal arteries very sclerotic, discs a little fluffy at the margins. Wassermann reaction negative. Urine: 60 oz., specific gravity 1003, trace of albumin. R.U.C. = 4.4/0.9.

Practically the same results were secured just before death, which took place seven weeks later and was due to cerebral haemorrhage. Transitory mild convulsions and delirium occurred in the third and fifth weeks and lasted six and thirteen hours respectively. Post mortem the kidneys revealed no appreciable abnormality beyond considerable sclerosis of their arteries.

The wide range of function had clearly distinguished the condition from that of chronic interstitial nephritis. Similarly, another case was differentiated by a range of 1.5/0.4; the blood urea was 0.045 per cent.

The influence of failure of the circulation on the test must always be borne in mind. Renal-vascular stasis gives rise to slow glomerular filtration and, consequently, promotes concentration of the urine. The "A" and "B" values are raised and their approximation varies directly as the degree of heart failure. The occurrence of oedema and the presence of albumin and perhaps casts in the urine, which is also of low chloride content, increase the resemblance to the findings in hydraemic nephritis. However, the history, the general appearance of the patient, the onset and character of the oedema, and the state of the heart, lungs, and liver, usually make the distinction easy. Cases in which heart failure and renal disease complicate one another can only be diagnosed as such, and the primary or predominant lesion assigned to one or other organ, by careful appraisalment of all the data available. In this connexion the blood pressure is often of great assistance, for when the heart is failing as the result of renal damage one finds the overload represented by high systolic and diastolic readings. Early, both pressures had risen, the systolic more so than the diastolic, then, as the heart flags, the former drops somewhat, and, finally, as full cardiac defect supervenes, both fall.

Range of Function as Gauged by Specific Gravity Determinations instead of the Concentrations of Urea.—This method is generally of considerable value when estimations of urea are not feasible. The test is carried out in the same way, except that no dose of urea is given; it is really nothing more than the water test already mentioned. The following examples require no comment: Normal 1020/1005, chronic parenchymatous nephritis 1020/1018, chronic interstitial nephritis 1005/1004.

#### Other Tests.

(a) Blood urea or blood non-protein nitrogen estimations as indices of renal inefficiency are not quite as sensitive as the range of urea concentration test, often much less so—for example, in hydraemic nephritis they usually yield normal figures. Results above normal, however, constitute valuable confirmatory evidence. The R.U.C. test has proved the better guide in prognosis.

(b) The uric acid, creatinine, and diastase determinations in the blood have seldom, if ever, shown any superiority in diagnosis over the above tests considered together with the clinical picture; as routine procedures they are impracticable.

(c) Inorganic Phosphorus Content of the Plasma.—The work of de Wesselow, in showing the value of this estimation as an aid to the immediate prognosis in azotaemic nephritis, is worthy of note. In the twelve cases that I have investigated in this way the concentration of plasma phosphate (P 0.004 to 0.014 per cent.) was proportional to the gravity of the condition as indicated by the clinical examination, the range of kidney function, and other findings. The reader is referred to de Wesselow's comprehensive paper.\*

(d) The diastase content of the urine has proved of very little assistance.

(c) *Dye tests* have their value in surgical practice. In "medical" cases they yield results comparable to, but not so uniformly reliable as, blood urea estimations.

In conclusion it may be stated that special importance is attached to the following in the diagnosis and prognosis of chronic renal disease: (1) History of the case. (2) General condition of the patient. (3) State of the heart, blood vessels, and blood pressure (systolic and diastolic)—an estimate of cardio-vascular efficiency. (4) Condition of the retinae and discs. (5) General examination of the urine. (6) Range of urea concentration test. (7) Estimation of the blood urea and perhaps also the inorganic phosphorus in the plasma.

#### Summary.

Special attention has been directed to putting forward the plea that in estimating the function of the kidneys note should be taken not only of the degree to which concentration of waste products in the urine can occur, but also of the capacity of the kidney to produce a dilute urine. It has been shown that the power to concentrate urea is best determined over the night hours after a provocative dose of urea, and that the value of the result obtained is much enhanced by ascertaining the greatest extent to which water diuresis, most effective during the waking hours, can lower the concentration of urea. The minimum concentration provides a basis from which to judge the maximum, and vice versa, an expression of range of function or reserve power. The part played by the heart's action and blood pressure in determining these results has been discussed.

I wish to take this opportunity of expressing my indebtedness to Professor Langmead for his kindness in permitting me to make use of his cases and for much helpful advice.

## THE RELATIVE LOSS OF HEAT AND WEIGHT IN THE NEWBORN, AND THE TREATMENT OF SHOCK.\*

BY

A. LOUISE McILROY, M.D., D.Sc.,

PROFESSOR OF OBSTETRICS, UNIVERSITY OF LONDON.

(From the Obstetric Unit, Royal Free Hospital.)

### THE RELATIVE LOSS OF HEAT AND WEIGHT IN THE NEWBORN.

The initial drop in the weight of the newborn has hitherto been regarded as inevitable. As a rule the chief fall occurs in the first three days. The average loss is about seven ounces, and some authorities state that half a pound is within normal physiological limits. Various causes are assigned, such as adaptation of ante-natal and post-natal metabolism, loss of urine and meconium, and deficient nutrition until the mother's milk is fully established.

There is no doubt that some loss of weight must occur in the majority of cases, but the problem is whether the loss cannot be diminished. Weight cannot be regarded as an

FIG. 1.—Charts showing initial loss of weight in normal newborn babies: A, of multiparae (bathed); B, of primiparae (warmed).

absolute indication of the infant's welfare, but is one of the best signs of progress. Some time ago Professor Pembrey pointed out to me that the treatment of the normal newborn was irrational as compared with that of the premature, and deprecated the process of bathing as it entails loss of heat. Acting on this suggestion, some nine months ago I began to try new methods of treating newborn infants. A series of normal babies at term were cleansed at birth with olive oil instead of by bathing.

The results have been satisfactory, and now oiling has

been instituted as the routine method in the Obstetric Unit at the Royal Free Hospital. The babies are oiled after birth and daily until the day before they leave the hospital, when the mothers are instructed how to bathe them. They lose less weight than bathed babies, and in most cases regain their birth weights or reach even higher weights before leaving hospital on the ninth or tenth day. The cleansing properties of oil are not well understood in this country: babies treated in the manner described are just as sweet and clean as if they had been bathed in the ordinary way. The oil is, of course, wiped off again after application.

After treating a large number of infants I felt that still further improvement could be effected by reducing exposure to the air after birth, and thus avoiding loss of heat. Immediately after delivery the infants in one ward were wrapped in warmed blankets. On the cord being cut the child was at once transferred to a cot with warmed blankets and hot-water bottles, and kept there until oiled and dressed. The results in these cases were still further improved.

Appended are two charts displaying results of 160 normal cases selected at random. For purpose of comparison the

FIG. 2.—Charts showing the average loss of weight in 40 oiled and warmed babies and 40 bathed babies of multiparae, and 40 oiled and warmed babies and 40 bathed babies of primiparae (1 square = 1 oz.).

Records of temperature

(rectal) were kept of 100 warmed and oiled babies. The temperatures were taken at birth, one or two hours after, and after oiling. In almost every case there was a fall after birth and after oiling. The average temperature at birth was found to be between 99° and 100° F. In one or two hours it had dropped about 1 degree. After oiling it was further reduced 0.5 to 1 degree.

Strain during labour with shock to the infant is followed by a greater fall in weight than occurs after normal delivery. In forceps cases there is a considerable drop in the weight of the infant during the first three days. This is less marked when the child is not exposed to air or bathing. Premature babies and also those born by Caesarean section usually lose more weight than children born by normal deliveries. Early artificial feeding until the mother's milk is established in both these groups of cases has been found to give satisfactory results. The weight charts of twins show in many cases a parallel loss and gain of weight for each infant. In infants of mothers who have suffered from toxæmia the charts show a considerable loss of weight.

Feeding methods are not involved in the inquiry, but better results as to weight are obtained when the child is fed every three hours than when it is fed every four hours. The children were all breast-fed, but when the mother's milk supply was deficient supplementary feeds were given.

The decrease in infantile mortality during the first year has aroused much attention, but few realize that the decrease during the first month is comparatively small. To put the matter in another way, the improvement has been chiefly during the last eleven months of the infantile year. For instance, in 1905 the mortality per 1,000 for the first year was 128, between two and eleven months 86, and during the first month 42. In 1923 the corresponding

\* Read at a meeting of the Obstetrical Section of the Royal Society of Medicine, December 4th, 1924.

figures were 69, 37.5, and 31.5. According to the Registrar-General's records, deaths during the first month are mainly due to birth injuries and prematurity.

Probably much can be done to reduce mortality by improved methods at and after birth, but ante-natal treatment is the real remedy. The future of successful obstetric practice lies in skilled supervision during the ante-natal period. It is obvious that an infant whose mother has suffered during pregnancy from toxæmia or any constitutional disease has a reduced vital capacity. Any form of ante-natal treatment, therefore, which improves the mother's general condition and reduces the possible complications of labour will have a marked effect upon the newborn child.

Ante-natal correction of malpresentations, the treatment of cardiac complications by rest, the reduction of pain by the administration of sedatives during labour, and the stimulation of a failing foetal heart by strychnine, strophanthus, etc., must have a beneficial effect upon the welfare of the infant.

#### SHOCK IN THE NEWBORN.

The treatment of white asphyxia demands fresh consideration. As a rule blue asphyxia can be treated by clearing out the air passages and stimulating the skin reflexes.

In white asphyxia the usual method is to clear the air passages and immerse the infant in a warm bath, sometimes with the application of cold water to the head, followed by artificial respiration of varying and progressive degrees of severity, finally culminating in the Schultz method. This arduous effort probably satisfies the obstetrician that if he has failed to restore the infant he cannot be blamed for not having exercised his energies to their utmost capacity.

The late Dr. Gordon Ley pointed out that in such cases attention should be directed, not to establishing respiratory movements, but to relieving cardiac failure due to shock, usually caused by cranial compression, or in some cases by pressure upon the umbilical circulation. This is, I think, the correct view. The greater the strain upon the mother during labour the greater the shock to the infant. Respiration cannot be induced until the heart has adapted itself. What is required is cardiac stimulation and not inhibition. Much depends upon the amount of carbon dioxide in the blood for the stimulation of the respiratory centres. It is possible that the reserves for this purpose may be wasted in useless muscular movements carried out upon an infant with an enfeebled heart.

As soon as the child is born it should be wrapped in a warm blanket and its air passages cleared. The mucus should be sucked out of the trachea by a rubber catheter with a glass window enabling the mucus to be observed before it reaches the operator's mouth. The infant should be then left at rest in a warm cot. Gentle massage of the heart can be carried out under the blanket, and stimulants such as pituitrin (2 minims) and camphor given hypodermically. No movements should be permitted which involve the head or spine. It is difficult at first to abstain from artificial respiration; but experience has proved the efficiency of the alternative method, and shown that results are better than when more rigorous means are employed. Time, warmth, and rest will usually restore the heart's action if the shock has not been so severe as to be incompatible with life. In cases of blocked air passages artificial respiration may be advocated, but the use of the mucus catheter will generally be successful. Heart failure is not usually the cause of death in such instances.

After the administration of *scopolamine*, or morphine, or even of ether, during labour, the infant is often born in an anaesthetized condition. It must therefore be allowed time to recover.

I am grateful to my obstetric residents, Miss Langston and Miss Salmond, and to the students and sisters for assisting me in these investigations. A record of several hundred cases has been charted and classified by Miss Pritchard, whose services were available through the assistance of the Medical Research Council.

## EPIDEMIC ENCEPHALITIS SIMULATING ACUTE SURGICAL LESIONS OF THE ABDOMEN.

BY

G. H. STEVENSON, O.B.E., M.C., F.R.C.S.,  
M.R.C.P.Ed., D.P.H.,

UROLOGIST TO OUT-PATIENTS, GLASGOW ROYAL INFIRMARY; SURGEON,  
MINISTRY OF PENSIONS HOSPITAL, GLASGOW.

I AM taking the opportunity of reporting shortly on four cases observed by me during August, 1924, to put on record what appears to be a new development relating to the diagnosis of that extraordinary disease now so well known as "lethargic" encephalitis.

At present we are experiencing an epidemic of this disease in Glasgow, and it will be clear from my report how essential it is for those of us who are engaged in hospital practice to draw the attention of our colleagues engaged in general practice to the various forms which encephalitis may take. I may add that the diagnosis of the disease under the conditions of general practice met with in this city is of necessity a matter of the greatest difficulty, especially as many of the doctor will have had little opportunity of seeing cases formerly. It would seem that the qualifying adjective "lethargic" would hardly apply to the type of the disease I have seen lately, and the term certainly conveys a very wrong impression of the striking symptoms, at any rate in the earlier stages of the disease. It is pretty certain that many of the milder cases are treated for other conditions, and the danger of the disease becoming more widespread is very real.

All four cases described were admitted to hospital during the short period of one month (August 13th to August 28th as a matter of fact) as acute abdominal conditions, and subsequently three out of the four were diagnosed definitely as epidemic encephalitis and removed to isolation hospital. The fourth case is as yet not finally diagnosed, but the diagnosis appears to rest between encephalitis and tuberculous meningitis. This case shows that even when the resources of a large general hospital are available diagnosis may be difficult. The notes on the cases are of necessity short as the cases were observed for a brief time only.

#### CASE I.

Servicing soldier, aged 19. Admitted August 15th, 1924. The diagnosis on admission was perforated gastric ulcer, which had been changed from that of strangulated hernia. The patient gave a history of sudden onset of very severe pain in the left lower quadrant of the abdomen, and stated that he had received a blow in this region on August 13th. He had vomited freely prior to admission.

I did not see the patient until some hours after the diagnosis of perforated gastric ulcer had been made, and it was then quite clear that we were dealing with some acute nervous condition. My first impression was that the case was one of tetanus or strychnine poisoning, as on entering the door of the side-room in which he lay I found him in the position of opisthotonos and having marked spasm of almost all the muscles of the trunk and limbs. His mental condition was, however, lethargic, and in complete contrast to the spastic state of his body. Hyperæsthesia of the skin of the right side of the abdomen from nipple to groin was very marked, and on testing for this strong myoclonic movements were produced. The temperature was 97° F. and the pulse rate 60. He was unable to give a history of any symptoms. Having excluded the possibility of tetanus and strychnine poisoning so far as possible I made the provisional diagnosis of epidemic encephalitis, which was confirmed by a physician (Dr. Harrington) next morning. I was assisted in the diagnosis of this case by the fact that I had seen an almost similar case in the same room about a year previously. In this case, however, the pain started in the left arm, but was accompanied by similar generalized myoclonic movements.

The patient was removed in a few days, having run a completely apyrexial course with rather a slow pulse. Ophthalmic examination before removal showed oedema of both optic discs.

It is obvious in this case that the doctor who saw the case prior to admission had seen him before the onset of the typical myoclonic movements, which appear to follow and not precede the agonizing pain.

#### CASE II.

Miner, aged 41. Admitted August 20th, 1924. The diagnosis on admission was right-sided renal colic. The patient gave a history of having been seized with acute pain in the right lumbar region, which later shot down into the right testicle, simulating the pain of the passage of a stone. He had, however, no hæmaturia and no difficulty in passing urine.

He did not complain of headache, but two days after admission he began to have some disturbance of accommodation, not being able to say whether an object was near or at a distance. At this time he also commenced to have typical myoclonic movements of the right iliac region, most marked in the rectus muscle. He had very marked hyperaesthesia of the skin of the right side of the abdomen; deep pressure was, however, not very painful—apparently a fact of some importance in diagnosis. His knee-jerks were markedly exaggerated, and in a short time the myoclonic movements began to affect the left side of the abdomen as well as the right. The pain was of such severity that large doses of morphine were given. In the first twenty-four hours after admission he had no fewer than five injections of 1/4 grain without any apparent effect.

The absence of reaction to morphine in the cases which I have seen is very striking, and would seem to have some diagnostic importance. There happened to be a case of tetanus in the ward at the time, and I suggested that as the cases seemed very similar intramuscular injections of magnesium sulphate might be tried. This procedure seemed to make the patient so much worse that only two injections were given. The maximum temperature in this case during seven days was only 99°, and the pulse varied between 70 and 80, although it was obvious that the man was acutely ill and suffering agonizing pain.

## CASE III.

Miner, aged 40. Admitted August 27th, 1924. The diagnosis on admission was "acute abdomen"—(?) *strangulated hernia*. The patient gave a history very similar to Case II. Four days prior to admission he had some slight pain over the left inguinal region, which rapidly became worse and shot down into the left testicle. The patient described the pain as being "jerky" in character. He had vomited repeatedly, had fairly severe headache, and on admission had retention of urine. No hernia could be made out.

On admission there were strong myoclonic movements of both sides of the abdomen and marked skin hyperaesthesia. The knee-jerks were exaggerated and myoclonic movements of the legs were commencing. He complained of no eye symptoms, but lateral nystagmus was present, the significance of which was doubtful owing to his occupation. He had also severe pain in the left hand and the right foot. Again, the temperature and pulse were not above normal, and morphine had no effect on the pain; hyoscine, however, seemed to quieten the spasms.

## CASE IV.

Clerkess, aged 17. Admitted August 15th, 1924. The diagnosis on admission was *acute appendicitis*. The patient stated that on August 12th she was seized with acute pain on the right side of the abdomen. She had vomited repeatedly, was constipated, and had severe headache. Her temperature on admission was 102.8°, pulse 100, and respirations 22. During the period of observation the temperature remained moderately elevated.

When I saw her shortly after admission she was very restless and resembled a case of chorea. She was inclined to be hysterical, and her answers were unreliable. The skin of the right side of the abdomen was very hyperaesthetic, and deep pressure was not allowed. She had no local myoclonic movements, although generalized choreic movements were present. Her mental attitude was so peculiar that I decided not to operate and observed the patient for some days. In the interval I saw her own medical attendant, who told me that he had been in doubt regarding some of her symptoms, but had eventually diagnosed appendicitis. On August 17th, as she was still running a high temperature and fairly rapid pulse, I asked a physician to see her. He gave the opinion that he considered that we were justified in exploring the abdomen. I therefore opened the abdomen over the appendix region on August 18th. I found a perfectly normal appendix, but there were numerous enlarged mesenteric glands. I removed a gland for examination, and this was returned as being "chronic inflammatory."

Her condition did not improve after the operation and it was reported to me that she was becoming increasingly noisy at night, throwing off the bedclothes, taking off her nightdress, and behaving generally like a naughty child. During the day she lay perfectly quiet and resented any examination in such a manner that one got the impression of imbecility. The temperature remained high (103° in the evenings). The knee-jerks were absent at this period and she appeared to have a positive Kernig's sign. There was no neck rigidity and no very definite evidence of tuberculous meningitis, which had been suspected when the enlarged glands were found.

She was again examined by the physician, who now gave an opinion that the case might be one of encephalitis, although he would not say this definitely, the symptoms being so obscure.

If this diagnosis is correct we have a case beginning with abdominal pain and not developing the typical myoclonic movements, tending rather to pass straight into the more lethargic type of the disease.

Dr. Middleton has informed me (about September 10th) that the abdominal wound suppurated to some extent and that the condition of the patient has improved as regards pulse and temperature. She still remains in a curious mental condition, but has not developed anything else to make him give a definite diagnosis of encephalitis.

I merely quote the case as illustrative of one in which encephalitis had to be considered, although the definite enlargement of the abdominal glands might indicate another infection.

## Conclusions.

From the very limited experience of a surgeon in such cases I would say that the following points are of importance in diagnosis.

1. *Myoclonic movements*, if present to any extent, are characteristic of the type of the disease likely to be mistaken for the acute abdomen, and once those have been seen in a typical case the observer is not likely to mistake them for anything else, although in the cases reported those had evidently been mistaken for the movements of a patient in pain. The movements show themselves as fairly rhythmic contractions of groups of muscles, and not at all as the muscular rigidity characteristic of acute abdominal lesions. In the cases under discussion the recti and obliques were the muscles principally involved. Needless to say, a patient with an acute intra-abdominal lesion does not willingly move the muscles of the abdominal wall to any great extent, and it is very remarkable to observe the intense pain produced by the involuntary myoclonic movements in a patient suffering from encephalitis. Unfortunately the movements appear to follow the pain, the interval varying in length, and herein lies the difficulty in diagnosis.

2. *Eye symptoms* (double vision, disturbances of accommodation, nystagmus, irregular pupillary reflex) if present are of great value. Headache as a first symptom is also of some value, and pain in a site removed from the main site complained of would also appear to be significant, as in Case III, where there was pain in a hand and a foot in addition to the abdominal pain.

3. *Skin hyperaesthesia* in the cases I have observed has been very marked and has been much more widespread than is the case in the ordinary acute abdomen.

4. *Pulse and temperature* in three out of the four cases were hardly affected.

5. *Lethargy*, in the early stages of the myoclonic type of the disease at least, seems often to be notable by its absence.

The disease in the myoclonic form resembles tetanus in many respects, but the muscle spasms are in the nature of a clonus and there is not the tonic spasm found in tetanus. External stimuli, such as an examination of the patient or the banging of a door, tend to produce an exacerbation of the symptoms, and the spasms start in one group of muscles and afterwards spread over the body, retaining, however, their clonic character. Chorea and hysteria are also likely to pass through the mind of the medical officer examining such a case. I have already discussed the question of the acute abdomen.

My only object in trespassing on the physician's domain is to draw attention to the fact that these cases are being mistaken for surgical conditions, and I must apologize to my readers for the somewhat inadequate notes. I also write in the hope that others will give us guidance in the question of early diagnosis.

I am indebted to Mr. Paterson for his permission to describe the cases seen in his wards and to Drs. Harrington and Middleton for their help in consultation.

## SPONTANEOUS RUPTURE OF THORACIC AORTA.

BY

C. DUNDAS MAITLAND, M.B., F.R.C.S.ENG.,

HONORARY MEDICAL OFFICER TO OUT-PATIENT DEPARTMENT, ROYAL SURREY COUNTY HOSPITAL.

SPONTANEOUS rupture of the thoracic aorta as a sequel to an operation for gangrene of the leg is a sufficiently rare event to justify the following report.

A small, thin, rather cachectic-looking man, aged 49, had spent most of his life in mining work in Burma, where he had suffered from beri-beri and malaria. His work, he stated, was largely in wet boggy country, so that for years he was almost continually getting his feet bathed in water and mud. I was first called to see him about six months before his death for an attack of abdominal pain which was diagnosed by Dr. Paget-Jones (Horsley, Surrey, as due to appendicitis; I agreed with this diagnosis and operated the following day, removing a subacutely inflamed appendix. During the routine pre-operative examination

Dr. Paget-Jones noticed that the aortic second sound was not clear, and that there was a faint mitral murmur; the urine was free from albumin and sugar. The patient stood the operation perfectly and made an uninterrupted recovery, there being no disturbance of the heart or peripheral circulation as the result of the anæsthetic or operation.

Two months later his doctor again asked me to see him on account of acute pain and tenderness in the left scrotal sac and along the course of the left vas deferens. I found a condition of acute deferentitis and leucitis. Prostatic massage produced an exudate fairly typical of chronic gleet. At this time a history of gonorrhoea many years ago was obtained, but the patient persistently denied any history of syphilis, although pressed strongly on that point. He was treated by rest, urinary antiseptics, fomentations, and careful dieting, with the result that all pain and swelling disappeared in about a week, and he returned to his daily work, travelling up to his London office and appearing to be in his usual health.

Shortly after this his heart began to give trouble, and I again saw him in a condition of acute auricular fibrillation. At this time Dr. Paget-Jones had already got him under treatment; he was quite unable to walk, was slightly cyanosed, and severely dyspnoeic. In addition to the auricular fibrillation there was a rushing double mitral murmur with marked left-sided dilatation, and the aortic second sound was again noted to be a peculiar blurred type of note, though we were unable to detect any actual murmur. A very rigid course of treatment with graduated doses of digitalis and potassium iodide, combined with absolute rest and careful dieting for about two weeks, was followed by a very gradual return to normal activities. At the end of another month, Dr. Paget-Jones informed me, the patient had resumed his business life, and the heart seemed to have so completely recovered that nothing abnormal could be detected by stethoscopic examination.

About six weeks before his death I was again called into consultation. When I saw him he was suffering great pain in the legs, and both were showing blue-black patches of commencing gangrene below the knees, the right being considerably worse than the left. The history was that three days previously he had noticed some numbness in the feet "as if he were walking on wool" and that they felt cold; he, however, regarded that lightly, as he had often noticed the same feeling when they were constantly getting sodden with mud in Burma. The following day, however, a painful dark blue indurated plaque, about 3 inches in diameter, formed in the right calf apparently just beneath the skin. He then sent for Dr. Paget-Jones, who at once noticed a slight commencing cyanosis and coldness of the toes of the right foot and absence of pulsation in the dorsalis pedis, calcaneal, and popliteal arteries of both legs. He suspected the onset of gangrene, and diagnosed the indurated lump as a subcutaneous hæmorrhage. When seen by me the next day (fourth day after onset) it appeared quite certain that the right leg could not be saved, but we hoped that the left was not too far gone to recover. The heart was again fibrillating, though not so badly as in the previous attack, the mitral murmur had recurred, and the aortic sound was blurred and prolonged.

The patient was immediately removed to the Royal Surrey County Hospital, where Dr. Mitchell took charge of his medical treatment, which consisted essentially of 30-grain doses of potassium iodide three a day and daily intravenous injections of strychnin. This was continued for twelve days, during which time the feet were kept continually elevated, powdered with sterilized boric powder, wrapped in thick layers of sterile wool, and the whole cradle covered with a large radiant heat bath which was kept going continuously. Under this treatment the left leg recovered completely as regards colour, warmth, and sensation, but circulation could not be felt in any arteries below the knee. The line of demarcation on the right leg sank from just below the knee to midway between knee and ankle, and then became stationary, but remained quite aseptic and dry. Meanwhile the heart had improved so much that I felt justified in attempting amputation in the lower third of the thigh. The urine was carefully examined in hospital and found to contain a very slight trace of albumin, but no sugar or acetone. The blood Wassermann reaction was found to be positive. The blood count was normal except for slight leucocytosis with an excess of polymorphonuclear cells amounting to 85 per cent. The blood pressure was: systolic 160 mm. and diastolic 95 mm. Hg.

On the twelfth day of hospital treatment—that is, the sixteenth from the onset of trouble in the legs—I performed the amputation after first blocking the sciatic nerve in the buttock by a local deep injection of 20 c.cm. of 1 per cent. novocain solution directly into the nerve trunk. This was combined with a very small amount of ether to obliterate actual consciousness, and the operation completed in thirty-five minutes. The patient stood the operation remarkably well, and presented no signs of surgical shock. During the first five post-operative days everything appeared to be progressing perfectly. The flaps retained normal sensation, warmth, "starting pains" or pain of any description except a little soreness around the site of the injection in the buttock.

On sitting up the popliteal artery in the leg after its removal, it was found to have a lumen less than half the normal, and to have grossly thickened fibrous walls, but there was no naked-eye evidence of ulceration or calcareous changes in the intima of the vessel, and no thrombus was found. On the morning of the sixth day after operation the patient felt so well that, wishing to be unduly independent of nursing assistance, he sat up in bed, attempting to shave himself. He was then noticed by one of the nurses to fall suddenly forward without uttering a sound. The ward sister reached him two minutes later and found him dead.

#### Post-mortem Examination.

A necropsy was performed the same day and the following remarkable condition was found. The heart was dilated and the musculature felt hard and fibrous. The mitral valve appeared healthy, as did the whole of the endocardium with the exception of the aortic valves, which were thickened and more inelastic than usual, but not grossly diseased. There was a slight excess of clear fluid in the pericardium. The right lung appeared healthy, the left lung was collapsed and compressed to a very small bulk by a huge collection of non-coagulated and clotted pure blood which completely filled the whole of the left pleural cavity. The heart, aorta, venae cavae, trachea, and lungs and oesophagus were removed *en masse* to avoid any possibility of accidental injury to any part of the main vascular system, from which it was suspected such a rapid and profuse hæmorrhage must have issued.

It was then observed that no aneurysm was present, and that the aorta was rather smaller than normal and of uniform calibre throughout its length as far down as the diaphragm, at which level it had been divided for removal. The aorta was divided from end to end with very blunt-nosed scissors and then carefully examined for a rupture. This was discovered in the form of a 1 inch split situated on the convex surface of the aortic curve half an inch distal to the site of junction of the left common carotid artery. The thickened, rigid, brittle aortic wall was so grossly diseased that the artery cracked readily when bent or compressed between the fingers. This was due to the extensive calcareous changes which had taken place throughout the whole length of the vessel; calcareous plates 1 inch square could be stripped out without any difficulty. The muscular and external adventitious coats could be readily stripped from each other by simple traction with the fingers, and the calcareous plates appeared to be embedded in, and to have largely replaced, the muscular coat. No gross change was to be seen in the intima, though there were numerous small areas of shallow atheromatous ulceration and proliferation.

The whole history of this case points to the gangrene having been due to syphilitic endarteritis obliterans rather than to any embolic blocking. The most remarkable feature was that the patient should have been able to carry on a normal active business life and to survive successfully two general anaesthetics up to within such a short time of his decease with such an advanced degree of degeneration present in his main arterial channel.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### ANEURYSM OF A BRANCH OF THE RENAL ARTERY.

I was very interested in Mr. R. P. Rowlands's article in your issue of November 22nd, 1924 (p. 939), on aneurysm of a branch of the renal artery. I think the following case of painless hæmaturia may prove of interest, and was possibly due to the same cause.

A man, aged 59, previously quite healthy, consulted me on August 14th, 1924, for profuse painless hæmaturia of sudden onset. The urine contained a very large quantity of bright red blood, and in the first specimen seen was a ureteric cast. Microscopically there was blood only, and no neoplastic cells were detected. Later, very slight ureteric colic occurred, with tenderness of the kidney on the right side. There was no history of trauma or of previous pain. A radiograph negatived stone, but gave definite evidence of slight enlargement of the right kidney. Severe painless bleeding continued for three days. On the fourth day I succeeded in demonstrating by cystoscopy profuse hæmorrhage from the right ureter and a stream of clear urine from the left. Some of the urine from the left kidney was collected and was found to contain 2.2 per cent. of urea. Profuse hæmorrhage persisted for the next forty-eight hours, and on August 21st I explored the right kidney through the loin, having diagnosed provisionally renal neoplasm. The organ was adherent, enlarged, and deeply congested. No stone or difference in consistency could be detected. As the hæmorrhage was just as profuse and continuous as ever, and the patient was becoming definitely anæmic, nephrectomy was performed without first opening the kidney. The patient made an uninterrupted recovery.

On splitting the kidney, after removal, the knife bisected the pelvis a globular mass the size of an olive, which appeared to consist of laminated blood clot, exactly comparable to that found on the walls of some aneurysms.

#### Pathological Report.

The whole organ was sent to the Clinical Research Department, St. Bartholomew's Hospital. The reports were as follows:

"August 30th.—Macroscopically the kidney shows several subcapsular hæmorrhages and subepithelial hæmorrhages in the pelvis. There is a larger hæmorrhagic area in the pelvic fat, in close relation with the pelvis, measuring roughly 2 by 1 by 1 cm. A section has been prepared from this area. It shows irregular areas of hæmorrhage in the peripelvic fat. The kidney itself appears normal and there is no evidence of new growth. Around

the areas of haemorrhage organization is taking place, as indicated by the presence of fibroblasts. The haemorrhage is therefore pathological, and is not recent. The section gives no clue to the cause of the haemorrhage. There is one small area of haemorrhage in the cortex which, macroscopically, looks not unlike an infarct. Sections are being prepared of this. The possibilities appear to be that the area of peripelvic haemorrhage is: (1) an infarct; (2) due to a very small papilloma which has been overlooked; (3) due to a leaking aneurysm. Further sections are being cut in the hope of finding the cause of the condition, but from experience of similar cases the probabilities are that no cause will be found."

"September 6th.—Further sections of the area of peripelvic haemorrhage show a condition identical with that found in the first section. No cause for the haemorrhage can be found. The small area of cortical haemorrhage is not an infarct, but simply haemorrhage in the kidney substance."

I cannot help thinking that the haemorrhage in this case arose from a leaking aneurysm of a branch of the renal artery of the type described by Mr. R. P. Rowlands. A papilloma small enough to have been overlooked would hardly have caused such severe and continuous bleeding as occurred in this case. I have preserved the kidney and the sections.

Newquay, Cornwall.

G. B. RICHARDSON, F.R.C.S.

### BARLEY ITCH.

An outbreak of "barley itch" or "miller's itch" has occurred recently in several ports on the south coast of England. The first outbreak occurred among men handling a cargo of Moroccan barley shipped from Casablanca to Southampton at the end of August, 1924. I examined several men affected at that time, as well as others subsequently, and obtained a very typical history and picture of an infestation by mites.

Intense irritation on the forearms and neck begins ten or twelve hours after first handling the barley; it then spreads rapidly all over the body, but is less below the belt line than above. There were no symptoms of malaise.

The rash appears first as a pale irritating spot like a nettle sting; it is quickly surrounded by an area of bright erythema, giving the skin a puffy appearance, somewhat like measles. A small vesicle appears generally, but not always, at the site of the bite. It is extremely likely to be broken by scratching. After two or three days the irritation dies away, and the skin at the end of a week suggests strongly a heavy infestation by *Pulex irritans*, for it is dotted with brownish-red areas of pigmentation the size of a small pin's head.

On September 8th I examined a sample of the barley, which had been in the grain store a week, and found no mites present. I reported at the time that the mite was probably one of the Tyroglyphidae (causing "grocer's itch") or the Tarsonemida (*Pediculoides ventricosus*), a parasite of the grain moth and its caterpillar.

The grain is unloaded here by a mechanical elevator, and practically only the few men working in the hold were affected. The matter was therefore considered to be unimportant.

During October several ports received consignments of Moroccan barley, and the men, in spite of a rise of 10s. a day, became chary of handling it. At Sharpness the men absolutely refused to do so, and a mechanical elevator was introduced. This made much dust, which was blown into some cottages near and infected all the women and children at home at the time.

Another outbreak occurred at the beginning of November, and I was able to obtain a considerable addition to my knowledge of the cause—namely, that, in reply to questions as to weevils, etc., the only parasites observed by the men working were a noticeable quantity of the grain moth. Unfortunately the ship had gone, so the only samples obtainable were from grain which had been unloaded by the elevator. No *Pediculoides ventricosus* could be found in it.

Dr. Bridge of the Home Office and Dr. Davies, Port M.O.H., Bristol, were able to take samples from the hold of a ship at Bristol, and found quantities of the mite on the first slide. The analysts, to whom samples were submitted, suggested that the cause was the sharp spicules which break off the husk of the barley, but these could never produce a pale spot. The presence of a toxic

substance is too strongly indicated by this vaso-constriction for such a cause to be possible.

Several similar outbreaks have been reported in this country, such as those at the London docks and Colchester in 1913, where the same mite was the cause in consignments of cotton-seed from Alexandria. In Casablanca it is well known as "boorweesh," but native coolies are seldom affected. I am informed by H.B.M. Consul there that "white men never sit on the sacks of grain twice"!

Mr. Hirst, entomologist at the British Museum, recommends flowers of sulphur, dusted freely over the body and inside the clothes, as the best preventive measure. After infection I have recommended a hot soda bath, which certainly allays the intolerable irritation.

A. G. G. THOMPSON, M.A., M.D., D.P.H.,  
Assistant M.O.H. Southampton.

### TUBERCULOUS DISEASE OF THE STERNUM.

LITTLE reference is made to tuberculous disease of the sternum in the ordinary textbooks, except to say that it runs its course like tuberculosis elsewhere. The unusual clinical features of the following case seem to merit record.

A plumber's assistant, aged 16, was sent into hospital with "rheumatism and endocarditis."

**History.**—He had had no previous illnesses and, according to his mother, was working, apparently in his usual health, until twelve days before admission, when he complained of vague pains in the front of the chest and arms. There was no history of injury to the chest.

**Condition on Admission.**—He was thin and undersized, complained of pain across the front of the chest, and had a cough. The heart was rapid (136) and the sounds soft; no murmurs were heard. The percussion note was impaired over the left base, where the breath sounds were tubular. The temperature was 101° and the respirations 36.

**Subsequent Course.**—On the fifth day a swelling suddenly appeared over the body of the sternum and adjacent costal cartilages. It could just be grasped in the palm of the hand; it fluctuated and was pulsatile (the pulsations being synchronous with the heart beat), but not expansile. On deep pressure the sternum could be felt eroded about the middle of its body. There was also another smaller swelling in the lower part of the neck just to the right of the middle line; it also was fluctuant but not pulsatile; there was apparently no communication between the two swellings. On the sixth day a small fluctuating swelling appeared over the back of the left hand. This was needled and pus withdrawn.

The patient ran a rapid course downhill. The temperature was intermittent; the mouth and lips dry and parched. He lay propped up in bed, was troubled with cough, was restless and delirious at night. On the twelfth day the swelling over the sternum diminished greatly in size. On the fourteenth day a fluctuating swelling was noticed over the left hip. On the sixteenth day he died.

**Post-mortem Examination.**—The sternum was completely eroded about the middle, the body being divided into two parts and the jagged ends separated by about half an inch. There was a quantity of brownish gray-like pus beneath the sternum. The heart showed no lesions. Of the lungs, the right was normal; the left was bound down by pleuritic adhesions and the lobes were adherent to each other. On the surface of the lower lobe were large flakes of fibrin. The upper lobe was oedematous, the lower much congested, exuded beads of pus on pressure, and sank in water. The spleen was a little enlarged, and the kidneys slightly enlarged and pale. No important changes were found in the other organs.

The interesting features are the rapidly fatal course and the sudden appearance of the swellings.

### CERVICAL RIBS IN CHILDREN.

IN view of the very interesting paper in the BRITISH MEDICAL JOURNAL of November 8th, 1924 (p. 844), by Drs. A. H. Southam and W. J. S. Bythell, the following two cases of cervical ribs in children appear to be worth recording.

**Case 1.**—A female child, aged 4, was admitted to hospital for treatment of fibrosis of the left lung. A cervical rib on each side of the neck was easily palpable, that on the right side being particularly well marked. X-ray examination showed that cervical ribs were present, and that the anterior end of the one on the left side was apparently attached to the first rib. This child had been under treatment at the same hospital twelve months before, and, though repeatedly examined, the cervical ribs were not detected then. At that time no x-ray examination was made.

**Case 2.**—A girl, aged 14, was admitted to hospital for treatment of pulmonary tuberculosis. Cervical ribs were palpable on both sides of the neck, and x-ray examination confirmed this finding. In this case there was also congenital absence of the right thumb and scaphoid.

In neither case did the cervical ribs give rise to any symptoms; they were only discovered during routine examination. Case 1 is of particular interest in view of the suggestion put forward by Drs. Southam and Bythell that symptoms do not arise so often in children owing to incomplete ossification. Apparently, incomplete ossification may also account for the fact that these ribs are not usually detected by ordinary physical examination, since in this case at the time of the child's readmission the ribs were detected at once, whereas twelve months before they had not been detected, although the child had been examined frequently.

### CONGENITAL FAMILIAL JAUNDICE.

THE following family history may be of interest in that three children out of a family of six suffered from jaundice and survived to lead a healthy life.

A woman, now aged 40, suffered from jaundice from the first to the tenth day of her life; her mother was jaundiced at the same time. She married at the age of 25, and the history of her children is as follows:

1. Boy (born one year after marriage): no jaundice; healthy.
2. Boy (born four years later): jaundice first to tenth day; survived, healthy.
3. Girl (born eighteen months after No. 2): jaundice first to tenth day; survived, healthy.
4. Girl (born three years after No. 3): jaundice first to tenth day, when the child died.
5. Girl (born sixteen months after No. 4): jaundice first to tenth day, when the child died.
6. Boy (born two years and three months after No. 5): jaundice first to third day, when the child died.

Both father and mother are alive and healthy. The progressive nature of the result of the congenital disturbance is clearly indicated.

## Reports of Societies.

### CANCER.

At a meeting of the Liverpool Medical Institution on December 11th, 1924, Dr. JAMES YOUNG of Edinburgh read a paper on cancer, which is published in this issue (p. 60).

Mr. F. T. PAUL, opening the subsequent discussion, said his own conception of the cause of cancer was founded on observations extending over fifty years. No line could be drawn between normal tissue growth and cancer; a gradual transition could be traced from the embryo, through monsters, teratomata, mixed tissue growths, innocent tumours, and recurrent growths to cancer without a break. Every new growth was an erratic counterpart of the tissue in which it originated. These points showed that cancer was closely allied to normal tissue growth, and could not very well result from a microbe. He called attention to the exciting and controlling influences which regulated normal tissue growth, giving as an example the growth of a kidney after excision of the opposite organ. Cancer was subject to the same exciting and controlling influences. Given excessive excitation to growth or weakening of control, a possible cause was present for the growth of cancer. There was sufficient evidence to show that cancer only occurred in predisposed individuals; in such, he thought, the balance between excitation and control was disturbed. Formerly he had held the view that cancer was due to a local or general excitation to tissue growth, but recently he had felt convinced that it was a weakening of the controlling inhibiting influence that was the chief factor. In a condition like chronic mastitis, irritants, which excited growth, might very well lead to exhaustion of control. In a "predisposed" person—that is, an individual in whom this balance was imperfect—any influence which tended to excite growth would in the absence of growth control lead to new growth; this he believed to be the true pathology of cancer.

Mr. K. W. MONSARRAT said that the parasitic forms described by Dr. Young bore a close resemblance to those which he himself had isolated from cases of breast cancer some years ago, the life cycle of which he had described. He did not hold the view that cancer was invariably due to parasitic invasion. It had been demonstrated that repeated or continuous irritation was capable of turning somatic cells from their orderly course into the cancer type, and he saw no reason to doubt that the long-continued stimulation of a parasitic invasion in an organ like the breast might also bring about the same revolution. He had demonstrated that under certain cultural conditions an organism could be grown from most cases of breast cancer which had a cycle marked by a characteristic pleomorphism. He considered that therapeutic and protective measures, in breast cancer at any rate, might be based on these observations.

Professor BLAIR BELL said that only those who had followed closely the development of Dr. Young's investigations, and had had the advantage of personal acquaintance with him, could appreciate the amount of labour put into his quest, and the material sacrifices made. This work of Dr. Young had not escaped the traditional treatment of all originality: he had had detractors and critics. Professor Blair Bell suggested that evolution, variation, and even mutation, whether atomic or biological, would some day be expressed in terms of physical chemistry. He hoped that Dr. Young would be able to show that the "*Fungus youngi*" deserved a place with the numerous other agents that were believed to cause cancer, but which he personally regarded as being producers of a general precancerous condition in the cell.

Dr. J. G. ADAMI, from his own observations and from his knowledge of Dr. Young and the sincerity of his work, was prepared to accept Dr. Young's observations upon the pleomorphism of the organism discovered by him in cancer of the breast. Those observations coincided strikingly with the earlier observations of Mr. Monsarrat made in the late Sir Robert Boyce's laboratory twenty years ago. Monsarrat, indeed, had gone further and had evidently, by inoculation of his cultures, induced formative new growths of more than one order in the lower animals. To suggest that Dr. Young's results were due to imperfect technique was futile and a confession of conservative ignorance, so vast of recent years had become the mass of similar observations by bacteriologists of recognized standing upon bacterial pleomorphism. But while making this acknowledgement, he was far from ready to associate himself with Dr. Young in regarding this organism as in all probability the essential cause of cancer. Bacteria might be one cause. He accepted whole-heartedly Erwin Smith's remarkable studies upon the *B. tumefaciens* as the cause of crown gall in plants, and was quite prepared to find that there were in animals bacteria of that peculiar order or virulence which stimulated growth instead of bringing about cell destruction. He found it impossible to make any sharp distinction between benign and malignant growths. He had pointed out long ago how large a number of benign growths were truly teratomata of various orders originating from totipotent, multipotent, and even unipotent cells, misplaced during development. To demand that the action of bacteria must be added in order to bring about malignant growth was unnecessary. Taking, for example, chorion-epithelioma malignum, the most malignant of all growths, they knew that this originated from the chorionic epithelium, which normally exhibited physiological malignancy, invading and destroying the uterine tissues until its villous processes gained entry into the uterine blood sinuses. Were they to demand the presence of bacteria in the embryo in order to incite this physiological malignancy, or to explain the continued growth of these villi within the blood sinuses? He was thus prepared to hold that just as the causes of cell growth were various, so were the causes of malignancy.

Professor ERNEST GLYNN stated that it was generally recognized that bacteria were usually present in malignant growths. This did not mean necessarily that they preceded the onset of malignancy. On the contrary, they were probably often secondary invaders, entering the growth not only from the surface, but by the blood or lymph stream. The observations of Ford and others demonstrated that stray bacteria not infrequently entered the organs of

healthy individuals. If perchance these bacteria reached a malignant growth they would be more likely to survive and multiply there than in normal tissues. He asked whether Dr. Young considered the *Micrococcus neoformans* of Doyen to be related to the organisms he had found, and pointed out that vaccines of this organism had sometimes produced temporary improvement in malignant growths.

Professor C. E. WALKER said that while there was but little doubt that certain micro-organisms were among the causes of cancer, as they provided the necessary degree of prolonged irritation, it was difficult to believe that one particular parasite was the essential cause of cancer. At a certain stage in the processes involved in prolonged irritation, the cells sometimes adopted a new way of life and produced cancer. Very little was known at present about normal processes in cells and what influenced these processes. Until they knew more about these phenomena and what factors in the environment affected them, but little further advance in their knowledge of cancer was probable.

Professor J. M. BEATTIE said that Dr. Young had clearly demonstrated in his slides the presence of bacteria and fungi, but it would be unfair to criticize the views he based on those findings without first seeing and carefully examining the actual specimens. The weak point in his case was that he was not able to produce experimental cancer with his organism. The four positive results he obtained in over forty mice could not be considered, as spontaneous cancer was known to occur in mice. The varying form of the organism found was not against the view of there being a single causal organism; these forms were possible variations of one organism. Without agreeing with Dr. Young's view, there seemed no reason why his very careful and painstaking work should not be examined carefully and without prejudice, since there seemed no reason to deny the possibility of bacteria, not necessarily a specific bacterium, giving rise to irritation and producing cancer as far did.

Dr. YOUNG, in replying, said that with regard to the difficulty of the teratomata raised by Dr. Adami, where multipotent cells were infected a mixed tumour would be expected. Erwin Smith had shown that infection of multipotent cells with the *Bacillus tumefaciens* produced in plants a tumour analogous to a teratoma. In reply to Professor Glynn, he believed that the micrococcus isolated by Doyen many years ago was an alternative phase of the organism.

### GLYCOSURIA IN PREGNANCY.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, held on December 4th, 1924, the President, Dr. H. RUSSELL ANDREWS, in the chair, Dr. ARTHUR CROOK read a paper on the incidence of glycosuria in pregnancy.

Dr. Crook said that the number of cases of unselected pregnancies dealt with was 548, yielding 1,346 urinary examinations. The cases included 26 with complications. Of these 548 patients, 166 had glycosuria at some time of pregnancy (30 per cent.), 23 had glycosuria in more than one pregnancy, but not all (4 per cent.), 8 had glycosuria in all their recorded pregnancies (1.5 per cent.). Of the 166 cases, 40 were first noted before the twenty-first week, 126 first noted after the twenty-first week; the highest number were at the twenty-eighth week, the next two highest at the twenty-second and thirtieth weeks. The percentage of cases in which the glycosuria ceased before labour in those who had sugar before the twenty-first week was 59, and 32 per cent. in those with sugar after the twenty-first week. The patients in whom sugar was detected before the twenty-first week had no recorded signs of toxæmia, but those signs were reported more often in those who developed the sugar after the twenty-first week. No special incidence of septic infection was recorded. The average weight of the children was 7.2 lb. The sugar was absent from the fasting urine in most of the cases and was amenable to diet. Cases were related: (1) showing the occurrence of oedema of legs, pruritus, and hydramnios in both pregnancies associated with glycosuria; (2) a case in which large quantities of sugar were present (up to 400 grams per diem), also present in the fasting urine, which did not disappear from

the urine till six weeks after labour (premature). The patient's highest blood sugar, during pregnancy, was 0.136 after glucose; (3) a case showing in three successive pregnancies the association of glycosuria and albuminuria with pernicious vomiting; (4) a case illustrating the ante-natal death of the nearly mature foetus in glycosuria and hydramnios. Two cases of true renal diabetes associated with pregnancy had no abnormal symptoms or signs. The large majority of cases in which sugar was found in the urine during pregnancy were unimportant; this applied especially to those occurring in the period before the termination of the fourth month and those appearing at the end of pregnancy. There was a group of patients, mostly found at about the fifth month, which were more difficult in regard to prognosis. They frequently had had severe vomiting, associated with oedema of legs and hydramnios; the foetus might die, when nearly mature, before labour.

The President congratulated Dr. Crook on his record of clinical observations carried on over a period of sixteen years. There was at present a good deal of uncertainty about the correct class for some cases of glycosuria in pregnancy, in spite of much recent work on the subject, and the after-histories recorded by Dr. Crook were of value in helping to show the relation of continued glycosuria to diabetes. The President had found pregnancy in renal diabetes rare; in most cases of glycosuria in pregnancy the patient's health was not affected, and no special treatment was necessary.

Dr. KNYVETT GORDON said that very many women suffered from glycosuria at one time or another during pregnancy, the proportion being in his experience somewhat over 50 per cent. The great majority of these had no other symptoms and required no specific dietary or medicinal treatment. The same thing happened in regard to the output of urea. The urea content of the blood in normal pregnancy was found, as a rule, to be lower than the normal, and the same phenomenon occurred with regard to the glucose content of the blood. So in regard to both protein and carbohydrate, these occurred less in the blood and more in the urine than in non-pregnant women, or, as the physiologist would put it, the kidney threshold for both urea and glucose was lowered. The explanation, he thought, was that, owing to the increased stimulation of the kidneys, probably of an endocrine nature, they became more active during pregnancy. If this stimulus failed the patient was in danger of toxæmia, or even eclampsia. In the bulk of the cases cited by Dr. Crook the blood sugar had not been estimated, so it was difficult to say whether they were toxæmic or not. The most useful remedy for metabolic disturbances in pregnancy, whether in regard to protein or carbohydrate, was thyroid extract.

Dr. EVERARD WILLIAMS raised the question of the innocence of cases of glycosuria without hyperglycæmia in pregnancy. Further knowledge and experience of cases of renal glycosuria or diabetes innocens had shown that some of these subsequently developed into true diabetes. It would be well to bear in mind the possibility that some of these cases might be early cases of renal glycosuria, made manifest by the strain of pregnancy, as had been suggested in cases of so-called alimentary glycosuria.

### Neo-natal Loss of Weight.

Professor LOUISE MELLOR read a paper on some observations upon the relationships between the loss of heat and loss of weight in the newborn. (The paper appears in full at page 67.)

The President remarked that papers on subjects concerning the newborn infant were too rarely brought before the Section. He thought that some of the charts shown were very striking, and agreed that in cases of white asphyxia the less vigour used in attempts at resuscitation the more likely were they to be successful. The method of putting cold water on the infant's head had not been taught for many years.

Dr. KNYVETT GORDON suggested that the diminished loss of weight recorded in the oiled babies might be explained as being due to absorption of oil. That absorption from the skin of newborn infants readily occurred was

shown by a case in which the vagina of the mother was swabbed freely with violet-green; shortly after birth the urine of the baby was coloured with the same dye. Oily substances were, as a rule, more easily absorbed than watery solutions. As regards loss of heat, oil would retard and water accelerate evaporation, with consequent lowering of temperature. Some of the oil would possibly be used as a food.

Dr. CLIFFORD WHITE and Dr. BOURNE also discussed the paper.

### THE GROWTH OF POPULATION.

At the meeting of the Royal Statistical Society on December 16th, 1924, when the President, Mr. G. UDNY YULE, C.B.E., M.A., F.R.S., was in the chair, a discussion on his presidential address on the laws governing population was opened by Dr. T. H. C. STEVENSON, of the General Register Office. An account of Mr. Yule's views was published in the *JOURNAL* of November 29th, 1924 (p. 1014).

Dr. Stevenson began by referring to three recent papers on the question of population, by Bowley, Brownlee, and Yule (the last being the presidential address delivered on November 18th, 1924). He could not accept Dr. Brownlee's finding that there was little connexion between fertility and infant mortality, in view of the very much higher child mortality returned for large than for small families at the census of 1911, the ratio being about 3 or 4 to 1 for the largest as compared with the smallest, while with each increase in the size of family born the mortality returns also increased. It seemed impossible that a direct count like this of the mortality history of millions of families could be in such serious error as Dr. Brownlee's results would suggest. But perhaps the most important result arrived at by Dr. Brownlee was that the present reduced birth rate was only just sufficient to maintain a stationary population. This the speaker had no difficulty in accepting, and its significance could be appreciated by all, though it was probable that the momentum of the present fall would carry them to a considerably lower level than any yet attained. Mr. Yule had very wisely warned his hearers against the risk of attempting to prophesy the distant future of the population, to the no small relief of the speaker, who, on hearing the subject of that address, had asked himself, "Is Saul also among the prophets?" and had been very glad to learn that Saul in this case was not. Prophecy was a most dangerous function for the statistician to undertake, for it could only be based, statistically, on assumption of the continuance of recent conditions, and as to the future of these the one thing they might assume with safety was change. The principles on which the assumption of such continuity of conditions, if only it could be made, might be applied to the estimation of population seemed to him to have been correctly stated by Mr. Yule, but in one most important particular he believed that those conditions were actually changing during the latter portion of the period from which Mr. Yule's curves were derived, and that not only here, but in other countries also, especially Germany. The birth rate for Europe as a whole, which during the nineteenth century, so far as covered by the official records, had not varied very greatly, had taken a sudden downward plunge with the advent of the twentieth, and had continued to fall, at an accelerating pace, until the outbreak of war in 1914 spoilt the comparison. This was illustrated by figures and diagrams, and it was pointed out that Germany had been much more affected by this movement than England and Wales, whose birth rate decline during the fourteen years before the war had been very similar to that of Europe generally. This fact, little recognized in this country, was, no doubt, well known in Germany; and it was interesting to speculate how far it might have contributed towards fixing the date for putting Germany's war machine in motion. Mr. Yule had pointed out that the death rate had varied without reference to population conditions, and in view of what he had said it seemed to the speaker that the same statement had applied, in the opening years of the present century, to the birth rate also, which would make the future course of population all the more difficult to prognosticate. The very suddenness of the change suggested interference

with the laws of nature, as by increased practice of contraception, rather than a change in the laws of nature themselves, though even on that theory he found it very difficult to explain to himself why or how 240 millions of people had come to make such a radical change in their lives with such precipitancy and simultaneity.

Professor HOWLEY criticized the logistic curve adopted by Mr. Yule, and doubted whether it possessed any special advantages other than mathematical neatness. Dr. BROWNLEE was of opinion that the declining birth rate could not be wholly explained by conscious volition, and held that a physiological factor, some race quality, was involved; he emphasized the dangerous position in which the country stood, having regard to the continued decline of the birth rate. Sir WILLIAM FLEVENING thought that the decline of the birth rate had begun earlier than Dr. Stevenson suggested. Dr. MARIE STOKES referred to the immense mortality rate, based upon conceptions, in the poorest classes.

Dr. MAJOR GREENWOOD remarked that an attempt to estimate the future population by a method similar to that of Professor Bowley, but making allowance for the decline of mortality since 1910-12, led him to conjecture that the population of England and Wales in 1931 would not exceed 41 millions, or that of 1941 42.8 millions. Dr. HENRY DEXTER held that the general contentions of Malthus had not been weakened by modern work.

The PRESIDENT said that an examination of the curves of birth rates and death rates did not suggest any discontinuity such as Dr. Stevenson emphasized, and he (Mr. Yule) was still unable to accept the explanations tendered to account for the trend of the population curves.

### THE CARE OF LIFE POLICY HOLDERS.

At a meeting of the Assurance Medical Society held on January 7th Dr. OTTO MAY read a paper on life offices and the care of the policy holder. He said that the American assurance companies had done much in the way of organizing the care of policy holders, so as to give them special facilities for the prevention and treatment of sickness, thus helping to ensure a favourable mortality. The object of his paper was to indicate the main features of this work and discuss how far it would be desirable for British companies to undertake similar work. The possible health activities of an insurance company were of three kinds: (1) general propaganda, (2) the endowment of research, and (3) the care and treatment of individual policy holders.

Of the various American companies the Metropolitan Life Assurance Company of New York appeared to be the most active in these matters, and Dr. May gave a summary of its work. With regard to propaganda, this had been carried out on an enormous scale. Millions of pamphlets dealing with every conceivable health topic had been distributed; exhibits had been organized at country fair exhibitions, etc.; and the company had always been ready to co-operate with any community contemplating special sanitary measures, and to support, or if necessary oppose, any suggested measure, by lecture, film, and leaflet. In this way the company claimed to have defeated the passage of laws which would have interfered with vaccination and weakened the quarantine laws. Under the heading of endowment of research the company had subsidized many investigations in various diseases, such as cancer and epidemic poliomyelitis. Among these Dr. May specially mentioned the sum (200,000 dollars) allotted for the "Framingham demonstration," the object of which was to show how greatly the death rate from tuberculosis could be reduced by organized team work. Special propaganda was undertaken among the inhabitants of the town, the co-operation of the local practitioners was secured, an expert consultation service was organized, and arrangements were made for detailed examination of a considerable proportion of the apparently healthy population. The results as regards tuberculosis mortality were as follows: In the pre-demonstration decade the figure was 131 per 10,000, in the demonstration period (1917-23) the figure declined from 97.5 in 1917 to 38.2 per 10,000 in 1923. The rates were

compared with control communities of a similar character to Framingham. These showed in the pre-demonstration period 125.9 per. 10,000, and in the demonstration period 129.4 in 1917, gradually decreasing to 84.6 per 10,000 in 1923. Dr. May considered that these figures strongly supported the conclusion that a vigorous tuberculosis campaign might result in a greatly diminished mortality and hasten the practical elimination of the disease. Such a campaign carried out in this country would, he considered, require an outlay of about £15,000,000 a year.

The activities of the company in the care and treatment of policy holders were discussed by Dr. May under the separate headings of industrial business and ordinary life business. In the industrial group the principal work consisted in providing an organized service of sickness visitors free of charge. In addition, special health work had been done among juvenile policy holders, one of the most interesting having been the holding of large picnics in various parts of the country. The results of fifteen years' experience of the work had been summarized in the company's pamphlet, *Lengthening Life through Health Insurance Work*, in which the mortality for the ages 1 to 74 between the years 1911 and 1922 were compared with that of the United States Registration Area over the same period. The chart giving the death rate from all causes showed a decrease from 1911 to 1923 of 28.9 per cent., as against that of the Registration Area of only 16 per cent. It was interesting to find that the corresponding figure for the Prudential industrial policy holders, for whom there was no special health scheme, was for all ages 25 per cent., and for ages 0 to 70 26.1 per cent. From a study of the charts Dr. May was unable to satisfy himself that the figures necessarily proved the financial value of the health work. Among ordinary policy holders the outstanding feature of the work was the provision of facilities for periodical medical examination, free of charge. Examinations were offered every year or every second, third, or fourth year, according to the amount of the policy, and were conducted on behalf of the company by the Health Extension Institute of New York. In criticism of this scheme Dr. May pointed out that in many cases the examination could be only the preliminary to accurate diagnosis, and that to be of any practical value the company should be prepared to carry out the whole further investigation of any abnormality detected in the course of the examination. As regards the actual results of the service, the statistics for the years 1914-21 showed that only 2.49 per cent. of the number eligible actually underwent medical examination, a figure which did not indicate any great anxiety on the part of policy holders to avail themselves of the privilege. Moreover, of this number only about 30 to 40 per cent. took the trouble to appear a second time, and of those who did avail themselves of the privilege the highest percentage was among those who were physically fittest—that is, who were least in need of it.

Summarizing the results, Dr. May concluded that the scheme, though excellent in theory, was impaired by the want of a really effective diagnostic service and by lack of interest on the part of policy holders. With regard to the suitability of these schemes for this country, National Health Insurance was already in existence, with its sickness visitors for the insured; further, the approved societies undertook, to a large extent, the work of the sickness visitor of the Metropolitan of New York, and it would seem that much of the propaganda could be and should be carried out in this country by the Ministry of Health. Of the work described, the Framingham demonstration, with its co-ordinated scheme of central organization working in touch with voluntary associations, appeared to Dr. May to be of by far the greatest interest. In the case of venereal diseases the Ministry of Health had already, to a large extent, adopted a programme on similar lines, capable of extension into a wider scheme; and it would appear that any financial expenditure for health work that life offices might feel disposed to make should be in the direction of supporting the many voluntary organizations which would always be required to help such a national health service to full success.

## Rebuelus.

### PSYCHOLOGY AND THE SCIENCES.

EIGHT lectures delivered in the psychological department of the University of Oxford have been published in a small volume entitled *Psychology and the Sciences*.<sup>1</sup> The purpose of the symposium was to ascertain the views of specialists in allied branches of science as to the value of the recent advances in psychology. Each essay is written by a worker eminent in his own sphere of knowledge, and the book will appeal more especially to readers of wide outlook and philosophic bent. The volume is edited by Dr. WILLIAM BROWN, who provides an essay on psychology and medicine. Dr. J. S. Haldane writes on biology; Dr. R. R. Marett on anthropology; Dr. F. C. S. Schiller on logic; Professor L. P. Jacks on ethics; the Rev. A. E. J. Rawlinson on theology; Dr. M. W. Keatinge on education; and Dr. T. W. Mitchell on psychical research.

The various writers must have experienced some difficulty in knowing which particular type of psychology to consider in relation to their own science, for, as Dr. Schiller points out, there exist at the present moment at least nine distinctive and antagonistic schools, all to be reckoned with. Since there is no agreement amongst psychologists as to fundamentals, so that psychology may be at present described as consisting of a number of competing tendencies rather than as a unified body of knowledge, the contributors to the symposium are naturally unable to base their discussions on the same foundations. The reader has thus a certain difficulty in discovering exactly what it is that is supposed to be helpful or otherwise to allied sciences. Dr. Haldane looks on psychology as the most important form of knowledge, and would appear to include all the teleological and normative sciences within its boundaries. He takes the view that the whole of the moral, literary, and humanistic side of education represents psychology; it deals, not with ordinary scientific abstractions, but with living and concrete personality—with interests and values which express themselves in conscious behaviour. He regards the really good school or university as that which teaches practical psychology (using the term in the widest sense) well, and points out quite truly that the teacher who cannot teach practical psychology, whatever else he may be teaching, has missed his vocation. It is evident that the psychology which Dr. Haldane regards as an essential part of the equipment of the teacher is not so much the formal psychology of the schools, or a belief in one of the many current theories of human behaviour, as one which is based upon an almost intuitive understanding of the developing mind of a child. The practice of teaching, as also that of psychotherapy, is generally in advance of its theory. Successful teaching, and perhaps psychotherapy, will always be as much an art as a science, and the teacher cannot be merely a theorist in dealing with his pupil; he must enlist his heart, his intuition, and his intelligence, as well as his science, in the service of the task he has assumed.

In his essay on psychology and education Dr. Keatinge makes some timely comments on what he describes as the dangerous doctrine of self-expression. This is to the effect that children should be allowed to express all their natural tendencies, that instincts should never be repressed, that freedom to do as inclination dictates is the cure for all evils in education and will produce sturdy and serviceable citizens. He does not suggest that instinctive tendencies should not be expressed, but considers it well to insist that such expression is only a transitory aim and that the ultimate aim of education is widely different. He feels that this position may be clearer if the term "self-expression" is reserved for the expression of primitive instincts through relatively simple channels, while the term "self-realization" is used for the expression of the same tendencies through the techniques of the sciences and the fine arts, techniques which can be built up only through self-control, self-denial, unflinching effort, and much pain. As there is no reason to suppose that life will ever be a bed of roses, the growing generation must obviously be equipped with the

<sup>1</sup> *Psychology and the Sciences*. Edited by William Brown, M.D., D.Sc., M.R.C.P. London: A. and C. Black, Ltd. 1924. (Cr. 8vo, pp. vii + 184. 7s. 6d. net.)

qualities of courage and endurance to overcome the obstacles and difficulties of life which are inevitable. Self-expression is not far removed from selfishness, and, in any case, as Dr. Haldane reminds us, the conception of persons as self-existent units is untenable from either the philosophic, psychological, or ethical point of view.

In spite of its multiplicity of confused tendencies, recent psychology has done much to increase our knowledge of human nature. It has ceased to be a purely academic study and is now in a position to give some guidance in the practical problems of life. In course of time psychology may, as Professor McDougall has suggested, build itself up into the master science of human nature, a science which will provide for all the social sciences the foundations for lack of which they have long remained sterile. This interesting series of essays certainly leaves the reader with the impression that modern psychology has already exerted a considerable influence on those branches of knowledge to which it is most closely allied.

### THE NATURAL METHODS OF CURE OF PULMONARY TUBERCULOSIS.

TWENTY years ago the clinician was a pathologist. To-day, with an inconstancy not altogether discreditable to him, he has forsaken his former mistress and is courting a fresh one; indeed, he has gone further—he has espoused her; her name is Radiology. To judge from Dr. Jaquerod's book on the natural methods of cure of pulmonary tuberculosis, the union is a fruitful one. Strong and lusty is the progeny, in striking contrast to the puny weaklings of the earlier mate.

The pathological study of tuberculosis was valuable in so far as it threw light on the processes of infection, the method of spread of disease within the body, the percentage of normal individuals suffering from latent infection, and the type of disease resulting from different routes of invasion; but it is not an exaggeration to say that it gave an altogether misleading idea of the processes by which healing is accomplished under natural conditions. At autopsy the morbid anatomist saw bands of fibrous tissue round the hilum of the lung, puckered cicatrices at the apex, calcified nodules, pleural thickening, and other signs of tissue reaction, and he concluded that it was by a process of gradual and progressive sclerosis that the disease was brought to a standstill.

The clinician, however, by taking repeated skiagrams of the affected lung, has found that this is not the only method; there is another and extremely important one, operative particularly in early cases of the disease—namely, the process of resolution. When the patient first comes under observation he is suffering from a bronchopneumonic consolidation of part of one lobe; he is placed under sanatorium treatment, and is observed both clinically and radiographically. After a period varying from a few weeks to several months, the lesion begins to clear up; the signs in the chest grow fewer and change in their character, the shadows on the plate become less dense and more circumscribed in their extent, till finally they disappear altogether, leaving a picture which is with difficulty, if at all, distinguishable from that of a normal lung. This is the process of resolution—a process analogous to that by which an ordinary lobar pneumonia resolves, with this difference, that instead of taking a few weeks to return to the normal physiological state, it requires a period of several months or even of two or three years. It might be suspected that though this method of healing may occur in a few isolated cases, it could not be responsible for any significant proportion of the total number of recoveries. But reference to Dr. Jaquerod's book will soon correct this fallacy. For ten years now he has followed his patients carefully, taking frequent and successive skiagrams of the same lesion, with the result that he has been able to collect a large number of instances in which healing has occurred by this method. Reference to the numerous reproductions of actual photographs which he gives is sufficient to convince one of the correctness of his opinions.

<sup>2</sup> *Les Processus naturels de guérison de la tuberculose pulmonaire.* Par Dr. Jaquerod, de Leyssin, médecin-directeur du Sanatorium Grand-Hôtel, à Leyssin. Paris: Masson et Cie. 1924. (Roy. 8vo, pp. 121; 32 plates, 62 figures. Fr. 10.)

Most of those who have been engaged in the treatment of tuberculous patients have seen examples of this method of cure, but probably few will be prepared to agree with him as to its frequency. It is greatly to his credit that he has recognized its importance, and has, in a book short but full of careful records, expounded the reasons for which he has arrived at his beliefs.

### CLINICAL METHODS.

THE eighth edition of that popular handbook *Clinical Methods*,<sup>3</sup> which first saw the light twenty-seven years ago, has now, by the sudden and lamented death of Dr. Harry Rainy of Edinburgh, been revised by the remaining author, Dr. ROBERT HUTCHISON, who acknowledges the assistance of various colleagues, especially of Dr. John Parkinson, with whose help the description of cardiographic methods has been entirely rewritten.

The present edition is ten pages short of the seventh edition, noticed in our columns at the time (*BRITISH MEDICAL JOURNAL*, 1920, ii, 518), for, although additions have been made, such as Professor A. A. Hijmans van den Bergh's reaction for bilirubin with Ehrlich's diazo reagent, fractional test meals, the estimation of sugar and of urea in the blood, and the urea concentration tests, methods which have become obsolete have been omitted. There is a new colour plate showing the spectra of haemoglobin and its derivatives compared with the solar spectrum, and attention is now drawn to the rotary haemoglobinometer devised by Professor Arthur Hall of Sheffield, but the caution is thrown out that Tallquist's method, of which the rotary haemoglobinometer is a convenient variation, gives only roughly approximate results and cannot be recommended. The Schick test for susceptibility to diphtherial infection finds a place as an established method of clinical investigation, but the Dick test for susceptibility to scarlet fever and tests for hepatic efficiency do not appear to be included; probably the author has good reasons for waiting until they are more fully confirmed and generally employed.

In conclusion it may confidently be predicted that this favourite handbook will soon pass into a further edition.

### A MANUAL OF SURGERY.

MR. ALBERT CARLESS is to be congratulated on the appearance of the eleventh edition of the *Manual of Surgery* popularly known as "Rose and Carless." In this edition he has been assisted by Mr. C. P. G. WAKELEY. Dr. Cecil Bosanquet has revised and modified the pathological section; Mr. Charles Hope has brought the chapters on the diseases of the ear, nose, and throat up to date; and Dr. Ernest Playfair has dealt similarly with the subject of anaesthesia. There is probably no surgical textbook more popular than this. Its chief merits are its uniformity, that it deals with a vast mass of information in a clear and concise manner, and that it leaves few subjects unmentioned. It is therefore an excellent book for the student working for an examination in surgery. For the pass student it is certainly too full, and Fellowship candidates will find in it a very sound foundation. As a practical guide it is as useful to the surgeon in a large hospital as it is to one whose lot lies in remote places, for whose benefit many of the older forms of treatment are retained. As a book of reference to the general practitioner it is invaluable. In many places the text has been drastically revised. For instance, all that was said in the previous edition about the treatment of congenital pyloric stenosis has now been summed up under the head of Rammstedt's operation. In the section of orthopaedic surgery the separate discussion of infantile paralysis and spastic paralysis is welcome. The chapter on acute and chronic ulcers of the stomach has been brought up to date. The general form of the previous edition has been adhered to, and the number of pages is about the same. The chapter on military surgery is

<sup>3</sup> *Clinical Methods: A Guide to the Practical Study of Medicine.* By Robert Hutchison, M.D., F.R.C.P., and Harry Rainy, M.D., F.R.C.P. Edin., F.R.S.E. Eighth edition, revised. London: Cassell and Co., Ltd. 1924. (Crown 8vo, pp. xiii + 688; 17 colour plates, 150 figures. 12s. 6d. net.)

<sup>4</sup> *Manual of Surgery* (Rose and Carless). By Albert Carless, C.B.E., M.D., B.S. Lond., F.R.C.S., assisted by Cecil P. G. Wakeley, F.R.C.S. Eleventh edition. University Series. London: Baillière, Tindall and Cox. 1924. (Demy 8vo, pp. x + 1570; 634 figures, 17 plates and an x-ray supplement. 30s. net.)

retained in the appendix. There is considerable improvement in the reproduction of the illustrations in the radiographic supplement, and several new and well chosen plates have been added. The author, in his preface, utters a word of warning against the modern tendency to depend more and more on laboratory help, to the detriment of the acquisition of that clinical sense or instinct which is of such supreme importance to the building up of the character of the true surgeon.

After so many years of active surgery, and writing from a detached yet keenly interested point of view, Mr. Carless can look back upon this edition with much comfort and many happy associations.

### AMERICAN ENCYCLOPAEDIAS.

THE enterprise of American medical publishers in issuing large books of the nature of encyclopaedias is remarkable, and the reviewer toils after them in vain. What, indeed, can he hope to do with a set of ten volumes covering the whole field of medicine, or with another set of six dealing with treatment? He can do no more than indicate the general scope of the sets of volumes. The problem of how to keep abreast of the advances of medicine—to say nothing of surgery—grows every year more serious, more difficult, for the medical practitioner; he gets from week to week in the medical journals an account of that advance, but the time will come in a year or two when, in some emergency, he only vaguely remembers what he has read. The praiseworthy aim of the American publishers referred to is to supply him with a book of reference, and the plan of the loose-leaved volume from which the out-of-date chapter can be eliminated and replaced by a new one appears to be growing in favour.

It is, indeed, with no little chagrin that a doctor observes his familiar old textbooks lapsing so soon into antiquity. A very few only withstand the encroachment of the years. New diagnostic methods and modern therapeutic measures demand recognition, and hasten the demise of former favourites. When it comes to encyclopaedias of medicine, however healthy a sign their superannuation may be of the development of medical science, it is a serious concern for the practitioner who is perpetually confronted with the problem of how to keep up to date.

The editors and publishers of a new loose-leaf *Practice of Medicine*,<sup>1</sup> in ten volumes and a desk index, seek to ensure that its purchaser shall be kept up to date by the annual issue (at the price of thirty-five shillings) of a series of new pages to replace what has become obsolete, and to furnish a continuous supply of recent knowledge. This encyclopaedia is edited by Dr. FREDERICK TICE, head of the Department of Medicine in the University of Illinois, with the assistance of three advisory editors—Dr. Luther F. Warren in medicine, Dr. Julius Grinker in neurology, and Dr. Julius Friedenwald in gastro-enterology. They have had the assistance of no fewer than 130 contributors. The volumes, including the desk index, are handsomely bound in black leather. The typography is good, and the index has been so adjusted as to make ready reference easy. The standard of the contributions throughout is excellent. There are numerous illustrative plates and diagrams, and an adequate bibliography supplements each article. The work reflects the recent progress of medical research in the proportionate amount of space devoted to such subjects as the investigation of the functional capacity of various organs, which is considered at length in the chapters on "Functional diagnosis" in volume ii. It is impossible to enumerate the principal contents; and it might be invidious to single out any article for special praise. The impression gathered is that the whole work has been admirably planned, and reflects great credit on the contributors and the editors. The clinical features of the various diseases are clearly outlined, and the pathological basis is succinctly and ably presented. The description of therapeutic methods is full, and the standpoint throughout is

modern but yet sufficiently conservative. There are no separate indexes for each volume. These are replaced by the single desk index, to which reference has already been made. Its arrangement presupposes an ordinary familiarity on the part of the reader with the various relationships of the different aspects of a disease, and so needless repetition is avoided.

The other encyclopaedia to which we have referred is the fourth edition of the *Encyclopedia of Treatment*,<sup>2</sup> formerly edited by Drs. Frederick Forchheimer, Frank Billings, and E. E. Irons. It has been revised by Professor GEORGE BLUMEN, M.D., of Yale. In the preface to the first edition Ziemssen's *Handbuch der allgemeinen Therapie*, 1883, is noted as a forerunner. The list of contributors includes more than 150 names, and each section ends with a long list of references. As an encyclopaedia it includes information condensed from all sorts of special works and articles. But there is the essential drawback that the information cannot be brought up to the date of publication. Thus, on the insulin treatment of diabetes (vol. i, p. 699) we read: "It is too early to reach definite conclusions as to the ultimate value of insulin, but so far the results are encouraging (Banting et al.)." The papers by Banting referred to were all published in 1922. Turning to volume vi (p. 237), on the treatment of spinal cord syphilis, the account is very general, and the references seem to relate to publications during the ten years preceding 1922. Each volume is supplied with an index, and there is a composite index in a final separate volume.

### BACKWARD CHILDREN.

THE book on nervous children (*Les Enfants Nerveux*)<sup>3</sup> by Dr. ANDRÉ COLLIN does not deal with children who are nervous, precocious, or neurasthenic, but with those who are mentally deficient, and especially with minor degrees of retardation. It is a plea for early diagnosis and classification of all mentally deficient children, and for their special study and direction before and during the school period. The mental evolution of the normal infant is described; and a brief sketch is given of the successive stages by which the cortical and subcortical centres of the brain take over the control of the sensory, motor, and intellectual functions of the body. A classification of types of mental defect is then presented. Finally, the professional orientation of mentally defective children is discussed. This, indeed, is the principal object of Dr. Collin—that the State should obtain the best service from this group of defective units. If this is to be achieved, the important facts in the mental evolution of the child must be known: the dates of teething, of the acquisition of walking and speech; the behaviour and attainments of the child in school, not omitting a consideration of his aptitudes and tastes; and, finally, a trial of these children after school age by a carefully supervised apprenticeship in various trades and occupations. The subject is important, and one in which the co-operation of the doctor, the school teacher, and the social worker is needed; the book is of value in indicating the complexity of the problem, and how little as yet has been done to deal with it.

### NOTES ON BOOKS.

THE compact little volume on septicæmias and bacteriæmias,<sup>4</sup> by MM. E. VAUCHER and P. WÖRINGER of Strasbourg, consists of twenty-five chapters with an introduction by Professor Vidal. The first two chapters deal with the pathology and symptomatology of septicæmias in general, and the following twenty are devoted to a consideration of the different varieties of septicæmias, including not only the well recognized forms, but also those due to micro-organisms of the Pasteurella group, the fusiform bacillus, *B. faecalis alkaligenes*, and *B. lactis aerogenes*. Surgical and purperal septicæmias are discussed in a chapter by themselves, and

<sup>1</sup> *Practice of Medicine*. Edited by Frederick Tice, M.D. Foreword by M. W. Ireland. London Agents: Butterworth and Co.; Hagerstown, Maryland, U.S.A.: W. F. Prior Company, Inc. 1924. (Snp. 20v. 8vo. Cash price for ten loose-leaf volumes and desk index bound in leather, 20 guineas. Special terms can also be arranged. A yearly service of new pages will be issued periodically, the cost of which will be £1 15s. per annum.)

<sup>2</sup> The George Blumer edition. . . . . *Therapeutics of Internal Diseases: Care and other than Surgical*. Edited by London and New York: D. Appleton and Co. . . . . (Roy. 8vo; Illustrated. Six volumes and index, £13.)

<sup>3</sup> *Les Enfants Nerveux*. Par le Dr. André Collin. Paris: J. N. Baillière et Filz. 1924. (5x7 in. 15s. Fr. 63.)

<sup>4</sup> *Septicæmies Septicopurphères-Bactériæmies*. By Dr. E. Vaucher and Dr. P. Wöringer. Préface by Fernand Vidal. Paris: Octave Doin. 1924. (4½ x 7½, pp. xv + 456. Fr. 18.)

nearly sixty pages are taken up by a careful consideration of the various septicaemias met with in the newborn infant. The last three chapters are devoted to clinical and bacteriological diagnosis and treatment of septicaemias in general. A remarkably full bibliography, arranged according to the chapters, is appended. The writers are to be congratulated on their work.

CALDWELL'S *Volumetric Analysis*<sup>3</sup> is a book intended mainly for medical and university first-year science students. It is a matter of no small difficulty to prepare a course of study in chemistry for a particular class of students who for the greater part of their time are occupied with other studies. The prime necessity of directing the work along lines suited to their special needs is over a danger to the survival of a more important object—namely, that of teaching chemical science as a thing distinct from a selected group of chemical facts. In no case does this danger occur more obviously than in teaching chemistry to students of medicine. The author of this volume has handled the difficulty with circumspection. He has produced a useful volume giving a clear exposition of the subject-matter. Whether it is scanned for the finer elements of instruction or scrutinized for the absence of essentials, it bears the examination well. What has been omitted can be conveniently taken up by the student at a later stage. It is not well to obscure the landmarks of a new region to a beginner's view. This is likely to be the effect of giving too plentiful information. We note, however, the omission of a test which we regard as too important to be excluded—namely, the perchlorate test for potassium. Assistance has been borrowed from the art of the printer with good effect in the arrangement and spacing of the text as well as in the choice of plain and leaded type. A description of solubility should be more cautiously expressed than that under strychnine, where the sentence occurs, "It is only sparingly soluble in water . . . whilst it is insoluble in alcohol. . . ." These two statements are only permissible when used for different comparisons. Occurring as they do in the same sentence they are misleading, for little as is the solubility of strychnine in alcohol it is many times greater than in water. But this fault must not be allowed seriously to detract from the author's work. The book that contained nothing needing amendment in a future edition would indeed be a remarkable production. Since it is an excellent book we anticipate that opportunity for revision of its very few defects will not be long delayed.

Patrick Branwell Brontë<sup>4</sup> is the subject of an essay by Miss ALICE LAW, who, brought up in the neighbourhood of Haworth, has been imbued with the interest of the tragic Brontë family. She stands up with a vigour that must command respect, though it does not bring conviction, for the memory of the brother of the three phenomenal girls, and argues that the black sheep of the family and not his sister Emily (Ellis Bell) was the real author of *Wuthering Heights*. Among the illustrations is one of "The Withens," Haworth, the supposed site of *Wuthering Heights*.

<sup>3</sup> *Elementary Qualitative and Volumetric Analysis*. By William Caldwell, M.A., Sc.D., with an Introduction by C. S. Gibson, D.B.Sc., M.A., M.Sc., F.I.C. London: J. and A. Churchill, 1924. (Demy 8vo, pp. xxiv+418, 10s. 6d. net.)

<sup>4</sup> *Patrick Branwell Brontë*. By Alice Law, F.R.S.L., F.R.Hist.S. London: A. M. Philpot, Ltd., 1924. (Cr. 8vo, pp. 192; 6 illustrations, 6s. net.)

## MEDICAL AND SURGICAL APPLIANCES.

Dr. NOEL F. V.D. Clinic, (Sunderland)  
writes: The Company has made for me a urethral probe, which I venture to think will be found to be a considerable improvement on other types. It consists of a rod six inches long, the distal end of which is roughened for the attachment of cotton-wool, and terminates in a smooth acorn tip which permits of easy introduction into the female urethra. For use, the wool is attached to the roughened portion and the acorn tip is left bare. Swabbing with this instrument is smooth, painless, and speedy.

wool, and terminates in a smooth acorn tip which permits of easy introduction into the female urethra. For use, the wool is attached to the roughened portion and the acorn tip is left bare. Swabbing with this instrument is smooth, painless, and speedy.

**X-ray Apparatus and Material.**  
We have received from Messrs. Watson and Sons (Electro-Medical), Limited, of Sunic House, Parker Street, Kingsway, London, three leaflets containing particulars of the firm's x-ray apparatus and material. One of them describes the general principle and purpose of the Potter-Bucky diaphragm for eliminating scattered radiation when making an x-ray examination of the deep parts, and advises a special form of this construction by the trade name of the "Sunic." The second leaflet describes the "Sunic" intensifier screen, which is the result of a special process for the production of extremely minute grains of calcium tungstate and for binding the crystals together as closely as possible with the minimum quantity of binding agent. The third leaflet is a list of second-hand and reconditioned x-ray and electro-medical apparatus offered by this firm.

## GUY'S HOSPITAL BICENTENARY.

MAURICE E. SHAW, M.D. Oxon.,  
MEDICAL REGISTRAR, GUY'S HOSPITAL.

ALMOST exactly 200 years ago, on January 6th, 1725, sixty patients were admitted to the newly built hospital "founded at the sole cost and charges of Thomas Guy, Esquire." In the course of the two centuries that have passed since the opening of what has for many years been known as Guy's Hospital, many hundreds of thousands of patients have found within its walls a resting place in time of sickness, where all the resources of medicine and the skill of the greatest exponents of the art have been freely given to them—the gift, not of the physicians and surgeons who from time to time have had the honour of serving upon the hospital staff, but of him to whose generosity and philanthropic spirit this great charity owes its origin, the founder, Thomas Guy.

The private life of the founder has been the subject of much rumour, and many stories are told that are hardly compatible with the character of the greatest philanthropist of his day. It must be remembered that in the eighteenth century it was a very remarkable, if not an entirely unique act, for a man to devote practically the whole of an immense fortune made out of business to the founding of a hospital for the poor. The advent of the millionaire—a product of the nineteenth and twentieth centuries—has led us perhaps to accept philanthropy on the large scale as more or less a commonplace of everyday life. Two hundred years ago it must have been relatively rare, and it is difficult to picture Thomas Guy as the parsimonious miser that some of the traditional anecdotes would appear to suggest. The story of his preferring to sit in the dark to discuss business rather than give rise to the extravagance of a farthing rush-light has been told of other great men and is doubtless quite unreliable. On the other hand, many stories of his philanthropy are told, even before he conceived his great project of building and endowing a hospital. Of these, one of the most attractive relates how Guy was looking moodily into the Thames at London Bridge one evening when an entire stranger, fearing he was some unfortunate at the end of his resources and contemplating suicide, came up and spoke a few encouraging words, at the same time pressing half a guinea into his hand. Years later Guy heard that his would-be benefactor had fallen on evil days and was in the throes of bankruptcy proceedings. He immediately went to the rescue and paid the debts, re-establishing the poor man in a business which prospered greatly in the future.

The truth about Guy probably lies somewhere between the two extremes. He was doubtless a hard-headed business man of great capacity and economical in his private habits, preferring to use the great wealth he thus accumulated for the benefit of posterity rather than on himself. It may or may not be true that his failure to marry was due to his annoyance at finding that his bride-to-be had exceeded his instructions in the matter of giving orders for repairs to the pavement in front of his house. But even if he had married it is doubtful whether his philanthropic projects would have been greatly modified, for he acquired the habit of philanthropy *pari passu* with the accumulation of his fortune, as is well illustrated by the town hall and almshouses which he built for his native town of Tamworth, and of which the former is still standing.

The main facts of Guy's life are so well known that there is little need to narrate them in detail here. It is, however, interesting to note that he was born off Fair Street in Bermondsey—a street still standing, and many thousands of whose inhabitants must at one time or another have been patients at the hospital he founded within so short a distance of his birthplace. His father was a coal merchant and lighterman, which makes it particularly appropriate that the hospital should have been so placed as to draw the majority of its inmates and out-patients from among the riverside workers and dock labourers. By trade Thomas Guy was a bookseller and publisher, and devoted himself especially to the publication and sale of

bibles. But the great bulk of his fortune was made out of the purchase of the tickets which were given by the Government to the seamen in the navy in lieu of pay. These tickets were commonly bought at a discount by speculators in the City in the hope of redeeming them later at par. Guy and others who speculated in this way have been much criticized, and have been accused of sharp practice in persuading the sailors to part with these bonds. The Governments of those days, however, were quite capable of repudiating such debts, and no doubt the sailors felt that 50 per cent. in the hand was worth 100 per cent. in the bush, and were glad enough to get ready cash at any price; the purchasers undoubtedly took a great risk, and might have lost heavily but for the permission subsequently given to exchange these for South Sea stock. Guy took advantage of this offer, and became possessor of some £45,000 worth of stock in the South Sea Company. By judiciously selling out before the final crash he piled up an immense fortune in a very short space of time.

The idea of building a hospital only occurred to Guy comparatively late in life. As a governor of the ancient foundation of St. Thomas's Hospital, then situated in the Borough High Street, he had been impressed by the poor provision made for the convalescent and incurable cases discharged from that institution. His first idea seems to have been to start a home for incurables as a complement to the existing hospital, but later his mind changed, and the hospital is described in Guy's will as "for the reception of four hundred poor persons or upwards labouring under any distempers, infirmities, or disorders thought capable of relief by physic or surgery; but who, by reason of the small hopes there may be of their cure, or the length of time which for that purpose may be required or thought necessary, are or may be adjudged or called incurable, and as such, not proper objects to be received into or continued in the present hospital of St. Thomas or other hospitals in and by which no provision has been made for distempers deemed or called incurable."

In 1721, when Guy was already about 76 years of age, land was obtained from St. Thomas's Hospital on the other side of St. Thomas's Street, and the building was begun in the following year. Guy lived to see the building completed and ready for the reception of patients, but died on December 27th, 1724, in his 80th year, just ten days before the first patients were admitted. The building as it was in 1725 represents but a small fraction of the present-day hospital. The two wings of the front quadrangle were added soon after the opening of the hospital. In 1850 Hunt's House, in which are now housed the medical and private wards and a large section of the out-patient department, was built from the proceeds of the munificent bequest of William Hunt, who died in 1829, leaving £200,000 to the hospital. Since that date building has been almost continuous, and round the eighteenth century nucleus provided by the founder has grown, or rather evolved, a modern hospital, with all the plant and equipment that a modern hospital involves.

The names of many famous physicians and surgeons are intimately connected with Guy's Hospital. Among the earliest is that of Richard Mead, who is reported to have stimulated Guy to found his hospital. However that may be, there is no doubt that Mead took an active part in assisting Guy with the planning and organization, although he was never physician to the hospital, being already on the staff of St. Thomas's. Mead is described as a highly cultivated, scholarly physician, the exact opposite of his great friend, John Radcliffe, with whom he shared a large proportion of the fashionable practice of London. He was in practice for some fifty years, and is said to have made as much as £7,000 in one year. Amongst his intimate friends were such men as Halley, Pope, and Isaac Newton.

The most famous of Guy's men are undoubtedly Astley Cooper, Bright, Addison, and Hodgkin. The former was by far the most distinguished surgeon of the day and had a phenomenal reputation as teacher. His position was richly deserved, for his capacity for teaching was only excelled by his skill with the knife. Chandler, a contemporary surgeon at St. Thomas's, said of him, "Sir, it is of no consequence what instrument Mr. Cooper uses, they are all alike to him, and I verily believe he could

operate as easily with an oyster knife as the best bit of cutlery in Laundy's shop." Like Mead, Cooper made an immense income from private practice, his biggest annual income being placed at £21,000, an enormous figure for those days. His biggest individual fee was received in unsuspected fashion. He operated on a wealthy inhabitant of the West Indies for stone in the bladder. On being asked his fee, Sir Astley Cooper replied, "Two hundred guineas." To which the patient responded, "Nonsense; I shall give you nothing of the sort. That's all I shall give you," and took off his nightcap and threw it at the surgeon. With his usual perfect manners, Cooper merely bowed, and put the cap in his pocket, saying "Thank you, Sir, anything is acceptable from you." On his return home he took out the nightcap to examine it and found it contained a cheque for 1,000 guineas.

Richard Bright's name is immortal owing to his discovery of the association of morbid changes in the kidney with albuminuria and dropsy. Thomas Addison will ever be remembered for his essay on disease of the suprarenal capsule and for his description of pernicious—or, as it is now more often called, Addison's—anaemia. Thomas Hodgkin was never appointed to the staff at Guy's. He was an applicant for the post in 1837, but Babington was appointed in his place. He was chiefly known for his article on "a peculiar enlargement of the lymphatic glands and spleen." Another great Guy's physician, Sir Samuel Wilks, many years later extracted from Hodgkin's work the material for the description of a new disease which, with characteristic modesty, he insisted on calling Hodgkin's disease. It would, perhaps, be more just to call it Wilks-Hodgkin's disease.

A great character at Guy's during the last century was the apothecary, James Stocker. He appears to have been a sort of Pooh-Bah and to have been competent in all his offices. He had especially a reputation for rapid diagnosis from the appearance of a patient. He had little science, but his long experience in the wards rendered his judgement uncannily certain. He once denied that a case was one of pyaemia on the grounds that patients with pyaemia never did their hair in that particular way. He was wont to observe that if, in a difficult case that might be typhoid or tuberculous meningitis, the patient resisted an attempt to pull down the bedclothes the case was probably meningitis; if on the other hand the patient took no notice it was more likely typhoid. This is still described in some books as Stocker's sign.

These brief and somewhat disconnected notes can hardly be brought to a close without some reference to the rivalry, and indeed bitterness, that sprang up between the residents of Guy's and St. Thomas's Hospital. There was always great competition to secure the "best" accidents, and the police were persuaded to patronize one hospital rather than the other by the quality and quantity of the beer they received as remuneration for their services. This state of affairs continued until the extension of the railway and the replacement of the old Bricklayer's Arms terminus by the new one at London Bridge led St. Thomas's Hospital to sell their old site and rebuild on the magnificent new one which they secured opposite the Houses of Parliament.

Now, on its two hundredth birthday, this hospital of Thomas Guy is appealing to the public for funds to enable it to carry on its work as a centre of healing, research, and education. By the end of the last century the original endowment began to be insufficient for the cost of maintenance. An appeal was made in 1896 with such good results that, by the end of the war, the hospital was able to meet its expenses with the aid of annual donations from King Edward's Fund, governors, and other benefactors. However, science is always advancing. A scientific institution, like a lady's dress, is always getting out of fashion and as constantly has to be replaced or readapted. And so it comes about that the extensive alterations and additions that the march of science has imposed upon all hospitals during the last five or six years has left Guy's Hospital with a debt of nearly £200,000. For this sum the president and governors are appealing, and it must be the wish of all medical men, whatever their school, that this modest birthday gift will be forthcoming.

# THE BRITISH MEDICAL ASSOCIATION HOUSE. WORK ON THE NEW BUILDING.

IN the JOURNAL of July 7th, 1923, a preliminary account was given of the fine building off Tavistock Square, Bloomsbury, which the British Medical Association had just acquired for its future headquarters. As most of our readers are by now aware, the building, originally erected as a college for the Theosophical Society, and employed for Government purposes during the war, is approached from one of the principal thoroughfares of London, leading from the terminuses of the northern railways to the modern centre of the metropolis. The lease is for 200 years, and the terms secured, both from the Disposal Board and from the trustees of the Duke of Bedford's estate, are advantageous.

The building, of red brick with white stone facings, which stand back in its own quadrangle, was designed by the eminent architect, Sir Edwin Lutyens, R.A. It was complete up to a certain point when taken over by the Government; but a great deal of work had to be done upon it, not only to the interior but to some parts of the outside as well, before it could be fitted to the purposes of the Association. The general aspect of the building when this work is finished is shown in the architect's drawing reproduced in Fig. 1.

Early last year plans, designs, working drawings, and specifications, were prepared under the direction of Sir Edwin Lutyens, and invitations to tender for the building and decorative work were issued. Of the estimates received from building firms, that tendered by Messrs. Ford and Walton was accepted. Apart from the seven weeks' delay due to the strike of building operatives last summer, the work has proceeded with great despatch. The unfinished ends of the north and south wings have been covered in with red tiles in harmony with the brickwork of the building. Ornamental wrought-iron railings and gates, to complete the main quadrangle and serve as a memorial to members of the Association who lost their lives in the war, are being made by the Birmingham Guild in consultation with the architect. The building, as it stands, has a total floor area of 48,000 square feet, including passages and lavatories, as compared with the 18,000 square feet of floor space at 429, Strand.

The volume of work needed to put the house in order for occupation has been very great, but much progress has already been made. The central archway leading from the main courtyard through the building into Burton Street at the rear, which was filled in temporarily with rough brickwork, has been cleared, and many other make-shifts have been removed. This archway, running beneath the Great Hall, gives direct access on the north side into the Library, and on the south into the Members' Lounge. The new Library is being fitted with the valuable mahogany pillars, panels, and bookcases from the old Library at 429, Strand; and the oak panelling and other woodwork has been transferred in like manner from the old to the new Council Chamber. The lighting and ventilation of the basement beneath the new Library and

FIG. 1.—THE BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, LONDON.

Lounge have been very greatly improved by excavating two areas in Burton Street and constructing basement windows. One of the largest pieces of work now in hand is the completion and decoration of the Great Hall—a large and lofty chamber running from end to end of the central block, and capable of seating more than 500 people. Some idea of the magnitude of this operation—which includes the construction of galleries and a dais, and an arched ceiling (weighing some 45 tons) at each end of the hall—may be gathered from Fig. 2, showing some of the builders' and decorators' scaffolding in situ. Not merely the Great Hall, but every part of the building, from basement to roof, is to-day a busy hive of workmen—masons, bricklayers, joiners, plasterers, painters, plumbers, electricians, and so on. The work is being pressed on with great energy by Messrs. Ford and Walton, and it is hoped that the whole

FIG. 2.—INTERIOR OF THE GREAT HALL, LOOKING NORTH, DECEMBER 1ST, 1924.

building will be completed in July next. Sir Edwin Lutyens has shown the keenest interest in all the plans for completing his building, and was in close touch with the work until his departure for India in connexion with the rebuilding of Delhi. After his return he will travel next April to New York to receive the gold medal of the American Institute of Architects.

SATURDAY, JANUARY 10TH, 1925.

## PROFESSOR PAVLOV.

PROFESSOR PAVLOV, the eminent Russian physiologist, is now more than 75 years of age, and yet he continues to publish research work and to direct the investigations of a group of younger scientists who have clustered round him. The earlier work of Pavlov is well known in this country, and has for many years occupied a prominent place in English textbooks of physiology, but his later discoveries have not received the same publicity, partly because Pavlov appears to be of a singularly modest disposition, and partly because much has been published in Russian scientific journals not available to many readers. This later work ought to be better known, and we propose to call attention to it, but before doing so our readers may be interested to have some details of the career of this venerable man of science.

Ivan Petrovitch Pavlov was the son of a village priest, and was born at Rjūsan in Russia on September 14th, 1849. He obtained his preliminary qualification to practise medicine in 1879, and four years later took the M.D. of St. Petersburg University. After two years' study in Germany under Ludwig and Heidenhain he returned to physiological research in Russia, but it was not until 1897, at the age of 48, that he was appointed to the professorship of physiology in the Military Medical Academy at St. Petersburg. During these early years of his career he developed a new method of approach to physiological problems, and perfected a technique peculiarly his own. The distinguishing feature of his early work is well described by Professor E. H. Starling in a character sketch which appears in the current number of *Nature*.<sup>1</sup> Improving on the customary physiological methods of the day, Pavlov set out to study the functions of the organs of the body as far as possible under natural conditions, thereby avoiding disturbing influences brought about by discomfort, pain, and the effects of general anaesthesia. Two examples will illustrate the precautions he took to keep the animals which were to be the subject of his experiments under the most natural and favourable conditions. His first papers, published in German in 1878-79, were concerned with the regulation of the blood pressure in dogs, and, in order to accustom the animal to the circumstances of the experiment, he trained a dog to allow the insertion of a cannula into a superficial artery on the inner side of the knee, and to remain quiet while the blood pressure was recorded. Again, when he first performed the classical experiments on dogs in which he provided a fistulous opening into the stomach and oesophagus for the purpose of studying gastric secretion, he could not be satisfied that the animals would receive sufficient care in his laboratory. He therefore took them home to his small flat, where they shared the comforts enjoyed by his wife and four children.

Although for many years every student of physiology has been brought up on Pavlov's classical work on digestion, a reference must be made to these experiments because they provided him with a technique which has served him in wider fields of research. His exceptional skill as an operator enabled him to make a fistulous opening into the oesophagus and stomach, and he observed that a few minutes after such an animal was given food a copious flow of digestive juice appeared through the gastric fistula. He found that even the sight or smell of food produced a psychical secretion due to the effect of appetite. He proved that the efferent channel for this reflex was by way of the vagus nerve; secretion could be stopped by section of the vagus, and began again after artificial stimulation of the cut vagus nerve.

After twenty fruitful years of study of the physiology of digestion, Pavlov came to concentrate his attention on the physiology of the nervous system, making use of the appetite reactions as an instrument for the study of the behaviour of the cerebral cortex. This study, which has occupied the last twenty years of his life, soon brought him to certain novel conceptions concerning the educable part of the central nervous system, the home of reactions learnt in the course of an individual's own existence. A preliminary account of this work was given by Pavlov in the Huxley Lecture delivered at Charing Cross Hospital in October, 1906. We can claim to have done something to bring Pavlov's later work into prominence, for the article by Dr. W. H. Gantt, entitled "A medical review of Soviet Russia,"<sup>2</sup> was a careful statement of Pavlov's point of view. We published also a report of the address on inhibition, hypnosis, and sleep, delivered by Pavlov at the eleventh International Physiological Congress in Edinburgh.<sup>3</sup>

To attempt to cover the whole of the ground on which Pavlov's rare genius has thrown new light would be far too big a task; we will refer only to three subjects about which his views deserve wider recognition—namely, the physiology of sleep, the transmission of acquired characteristics, and the question of trophic nerves.

It may be unexpected that experiments on the secretion of gastric juice should lead to a theory about sleep; but such is the case, and knowledge gained from these gastric reflexes has been turned to advantage in other directions. Pavlov distinguishes two types of reflex—the unconditioned and the conditioned. When acid or gustatory substances are introduced into the mouth of a dog a flow of saliva ensues. This is the "unconditioned reflex," an inborn connexion between an outside agency and corresponding definite activities of an organism. In contrast with this, any individually acquired reflex Pavlov describes as a "conditioned reflex." For instance, if some other kind of stimulus, such as the ringing of a bell, be associated for a long time with presentation of food or introduction of acid, this associated stimulus alone becomes sufficient to evoke a flow of saliva without actual presentation of food. This "conditioned reflex" must be due to the laying down of new paths in the cerebral cortex. A conditioned reflex, if not accompanied by the unconditioned, is temporarily suspended or inhibited. Now Pavlov holds that every conditioned stimulus, as soon as it is used alone, sooner or later leads to a drowsy state or to sleep. In his address at Edinburgh he gave an example of a dog which became drowsy and fell asleep after the repetition of the conditioned stimulus in the absence of

<sup>1</sup> *Nature*, January 3rd, 1925. The article is accompanied by a portrait in photogravure, which, judging from our recollection of Pavlov at the International Congress of Physiology at Groningen in 1913, is, allowing for the intervening years, an excellent likeness.

<sup>2</sup> BRITISH MEDICAL JOURNAL, September 20th, 1924.

<sup>3</sup> *Ibid.*, August 11th, 1923.

feeding.<sup>4</sup> He believes that the inactive state spreads from exhausted cells to others not involved in the work, as though the exhaustion of certain cells led to the formation of some substance capable of being carried to distant parts and acting there. The inhibition which we are always exercising during the waking state is to be regarded as a partial sleep—a sleep distributed in small parts and within narrow limits; generalized sleep is a diffused and continuous inhibition of the hemispheres, radiated over the whole area of active points of the great hemispheres and even over some parts of the brain which lie below the great hemispheres. Hypnosis he regards as an inhibition spread over the usually active points in special parts of the cerebral cortex. It must be admitted that the reasoning in this argument is not easy to follow, but we have not before us a full account of all the facts by means of which Pavlov supports this theory. We refer to this subject because of the conclusions at which Pavlov has arrived, and because it illustrates the unusual fertility of his mind.

These conditioned reflexes represent an individual attainment, and Pavlov turned to inquire whether or not they are inherited. This research has rekindled the old controversy as to whether or not acquired characteristics can be inherited; or perhaps it would be more correct to say that he has stirred up to a more lively activity fires that have been smouldering of recent years. In brief, he found that with the first set of wild white mice on which he experimented in order to establish the conditioned food reflex, using the sound of an electric bell, it was necessary to repeat the combination of ringing of the bell and feeding three hundred times in order to form a well established reflex. The second generation formed the same reflex after one hundred repetitions. The third generation acquired this reflex after thirty repetitions, the fourth after ten, and the fifth after five only.

A good account of Pavlov's views on trophic nerves was given by Dr. Gantt in the paper referred to above. Dr. Gantt remarked that the experience of clinicians, and especially of surgeons, has for a long time tended towards a belief in the existence of trophic nerves, whereas physiologists have been inclined to attribute so-called trophic changes to alterations in blood supply effected through vasomotor fibres. Well aware of this difference of opinion, Pavlov has always leaned towards the views of the clinicians that special trophic nerves do exist, and as the result of his own and his colleagues' researches has now satisfied himself that all organs and tissues have three classes of nerves—functional, vasomotor, and trophic. His opinion is best given in his own words: "Thus we would suppose that every organ is under a triple nervous control: (1) functional nerves, which may be inhibitors or exciters—for example, those nerves which produce contraction of muscle or the secretion of a gland, or inhibition of both of these functions; (2) vasomotor nerves, which regulate the bulk carriage of chemical materials and the taking away of refuse by augmenting or diminishing the flow of blood to the organ; (3) trophic nerves, which determine in the interest of the organism as a whole the exact quantity of material utilized by every organ."

No doubt many people in this country, having heard so much of the distress of the middle classes in Soviet Russia, must have feared that such distinguished scientists as Pavlov were hindered in their research work. It is reassuring to hear from the first-hand experience of Dr. Gantt that Communist officials take

interest and pride in the scientific institutions of Russia, and that the Soviet authorities have done what they could with limited means to keep science alive and to encourage its growth.

## THE POPULATION OF ENGLAND AND WALES.

Born in the leading article and in the correspondence columns of the *Times* the birth rate is now under discussion; the same topic had a principal place in the exchange of expert opinions at a meeting of the Royal Statistical Society, briefly noticed elsewhere in this issue (p. 74). If we are to reach the truth we must carefully distinguish between fact and theory; indeed, we must make a finer division—between undoubted fact, reasonable probability, and conjectural explanation.

Two undoubted facts are that the birth rate has been declining for more than forty years, and is now lower than it has ever been, in time of peace, before; and that the death rate has behaved in the same way. A third undoubted fact is that the rate of natural increase is declining. These are, indeed, the only undoubted facts. Reasonable probability, however, attaches to the following statements. The birth rate will continue to decline, so long as the present or any easily imaginable economic conditions prevail, and the death rate will also continue to decline, but not at a rate sufficient to prevent an increase of the crude (unstandardized) death rate. The decrease of death rates at ages cannot ultimately compensate the increased total mortality due to the increasing average age of the population. When the crude death rate will begin to increase is a question on the verge of reasonable probability; it is not likely to be delayed more than ten years at most.

We have now, perhaps, exhausted the reasonable probabilities, and pass into the field of conjecture. Within this field, however, are the really interesting topics. One, indeed, which seems to interest many people to the exclusion of all others—namely, whether the decline of the birth rate is due to deliberate "birth control," or whether "birth control" is an epiphenomenon—is, we think, of secondary importance. Obviously if, as Dr. Brownlee holds, "birth control" is a mere symptom, those who attack it are, from the racial point of view, wasting their breath. If, as Dr. Stevenson contends, "birth control" is the major factor of the declining birth rate, they are still, we believe, wasting their labour. A man may be induced by patriotic motives to die for his country, but hardly to procreate children for her, unless he can be convinced that those children will find places to fill at least as good as that he occupies. Rhetoric about race suicide, the decline of the empire, and so on, will never be accepted by the potential parent as a substitute for an economic guarantee.

The two questions, then, which seem to us of paramount importance are, first, what is likely to happen without some great economic change? and secondly, if the answer to this first question is gloomy, can any remedy be found? The answer to the first question is that within, at most, two generations the population will cease to increase at all, and that, owing to the rising proportion of elderly persons, its economic productive power will diminish. Mere decrease of population has been regarded by some as a great benefit, but those who use this argument have not always appreciated the consequences of reduction as effected under existing conditions. Let us suppose for a moment that

<sup>4</sup> BRITISH MEDICAL JOURNAL, August 11th, 1923, p. 257.

England and Wales, as an isolated unit, could support a population of 20 millions, and, with such a population, be entirely self-sufficing. If we could select from our present population of 38 millions 20 millions in the right sex, age, and occupational grouping, and dispose of the remaining 18 millions in some Utopia, England and Wales might be healthy and happy. But we can do nothing of the kind; we can only bring down the population to 20 millions by (1) reducing the birth rate and (2) emigrating population of the age, sex, and occupation groups which the British dominions and foreign countries will accept. When this had been done we should inevitably find that the 20 millions left at home were neither of the age nor occupational constitution that the isolated unit would need in order to be self-supporting. We should have far too many old people and far too few agriculturists. In other words, reducing the population as it is being reduced may not reduce the pressure of population at all; a smaller gross population with a larger proportion of non-producers may, indeed, render a territory not less but more overpopulated than ever.

We think, then, that Dr. Brownlee and Dr. Stevenson are right in viewing a probable further decline of the birth rate with apprehension, and that an answer to our second question is urgently needed. We, however, cannot give it; it is a problem of the higher statecraft. The medical statistician is entitled to call attention to the trend and probable future of our population; the death rate, which medical knowledge has done so much to diminish, is a factor of that trend; the national consequences must be weighed by others with the wider responsibilities of the statesman. We can only urge that these consequences should be weighed, and not obscured by idle rhetoric.

### THE OPIUM QUESTION AND THE LEAGUE OF NATIONS.

The two conferences at Geneva on the effectuation of the various provisions of the Hague Opium Convention of 1912, of the early proceedings of which we gave some account in the JOURNAL of December 6th, 1924 (p. 1071), suspended their sessions before Christmas and will resume work on January 12th. Discussions in the second conference, under the chairmanship of M. Zahle, have shown that it is not easy sharply to define matters touching the limitation of the production of opium and coca from the question, specially referred to the first conference under M. van Wetsum's presidency, dealing with the restriction and suppression of opium smoking.

Bishop Brent, the leader of the United States delegation, before returning to America expressed himself as profoundly dissatisfied with the results hitherto attained, and feared that support would be given to the accusation that Western nations with possessions in the Far East were indifferent to the welfare of the inhabitants of those possessions, and were content to have one law for the protection of their home population and another for the exploitation of dependent races. The three weeks' adjournment may afford time for reflection and reconsideration. Representations have, we understand, been made to the British Government that it would be well, in view of the important bearing of the opium question on the work of the League of Nations, and the inadvisability of alienating American co-operation on this and other pressing international problems, to strengthen the British delegation at Geneva, which has hitherto consisted only of Civil Service officials.

Time will also have been given for all the delegations to review the previous debates and digest the numerous reports of subcommittees and other data which have been collected. The proposals put forward for strengthening the provisions of the Hague International Opium Convention of 1912 are mainly two; first, those adumbrated by the Advisory Committee on Opium of the League of Nations, and secondly, the far more drastic amendments elaborated by the United States representatives. The latter include a provision to reduce by 10 per cent. annually the imports of raw opium to be used for making prepared (or smoking) opium into those countries in which traffic in such opium is not altogether prohibited.

Among the reports of the various subcommittees is one dealing with the amount of opium required annually for medical and scientific purposes. It will be remembered that a mixed commission of the Health and Opium Committees had reported that the only legitimate requirements were medicinal and scientific, and roughly calculated 600 milligrams a head a year as the amount of such requirement. The new subcommittee now finds that estimate to be too high, and regards 450 milligrams as the maximum, while Professor Knaff-Lenz, from the examination of a large number of data, considers 400 milligrams of raw opium as sufficing for normal legitimate medical requirements. The subcommittee allows a round figure of 7 milligrams as the corresponding figure for cocaine.

Another subcommittee was of opinion, though not unanimously, that cannabis indica should be brought under control in the same way as opium and coca. Yet another subcommittee reported that in Bolivia coca leaves have been, and are, habitually used by the people, and, it is alleged, with no injurious results; that their limitation to medical purposes would be impossible; and, further, that in Java the coca shrubs are utilized as hedges, and that the leaves are never consumed or exported.

The attention of the second conference was drawn to opium-growing in Jugo-Slavia, and a commission has been authorized to inspect the poppy cultivation in that country with a view to possible prohibition. This action has called forth from the Jugo-Slavian Government the retort that "it is the main source of income in the southern provinces and is not hurtful to the people, who export, but do not use, the product." This rather naïve confession is reminiscent of Warren Hastings's observation in regard to India: "Opium is not a necessary of life but a pernicious article of luxury, except for purposes of foreign commerce only, and which the wisdom of Government should carefully restrain from internal consumption."

### PROFESSOR BERGONIE.

THE rapid progress made during recent years in radiology has been due in no small degree to the fact that those concerned have combined ingenuity and resource with a high degree of personal courage and self-sacrifice. This combination was very evident in the case of Professor Bergonié of Bordeaux, who died on January 2nd, after a long and painful illness, at the age of 68. His early studies were made under the supervision of Professor Merget of Bordeaux, whom he later succeeded. He devoted special attention to the electrical treatment of paralysis and muscular atrophy, and to the treatment of obesity by faradic currents. During the war he invented an electrical device for detecting bullets buried in tissues. In addition to directing the radiographical work of a large area of the

French army, he was sent on consultative missions to the Italian, English, and Belgian fronts. The greater portion of his professorial life was, however, devoted to the use of x rays, particularly in relation to the treatment of cancer. "Almost exactly eighteen months before his death he said: 'I have eighteen months to live. I shall devote them all to the fight against cancer.'" The first anti-cancer centre in France was founded by him at the Hôpital St. André, Bordeaux, and he twice received the gold medal of the Carnegie Foundation. In our issue of November 28th, 1924 (p. 1031), we announced the gift by Professor Bergonié of 100,000 francs to the Bordeaux Faculty of Medicine, for the installation of a new institute in furtherance of the cancer campaign. The curative properties of radium in connexion with the treatment of cancer were also studied by him. For a long time he had had a sad personal experience of the dangers associated with the use of x rays, and the steady progress of disease in his own case was unchecked by amputations. Shortly before his death he received the Grand Cordon of the Legion of Honour as a tribute to the great value of his life's work. Marshal Pétain made the presentation on December 14th, when laying the foundation stone of the new cancer institute of the Hôpital St. André, the plans for which had been drawn up by Professor Bergonié. Acknowledging the honour received from the leader of the forces at Verdun, Bergonié, in almost the last words of his life, gave expression to the same indomitable courage, which inevitably paves the way to victory, however long delayed.

#### DEVELOPMENTS IN PUBLIC HEALTH TEACHING.

We have referred recently to some interesting developments in research which are being made by the London School of Hygiene and Tropical Medicine at the present time, in co-operation with the authorities of Southern Rhodesia, of the Zoological Society of London, and otherwise. The practicability of early developments in the teaching of public health is also being explored. A course in parasitology has been arranged by the school authorities in the tropical division of the school as a supplement to the teaching in other subjects for the diplomas in public health which is being given at the present time at other recognized teaching centres. The tropical division of the school (the old London School of Tropical Medicine at Endsleigh Gardens, Euston) was taken over by the new body on August 1st last, and the new course in parasitology is being given by the heads of some of the departments of this school. The course includes lectures and practical demonstrations in entomology by Colonel Alcock, F.R.S. (January 12th to January 22nd), in helminthology by Professor Leiper, F.R.S. (January 26th to February 11th), and in protozoology by Dr. Thomson (February 24th to February 26th). At the instance of the Board of Control a special course on the study of malaria, both from the clinical and laboratory standpoints, is being arranged in February for medical superintendents of mental institutions, for their guidance in the malaria treatment of general paralysis of the insano. Developments in the general public health teaching undertaken by the school will be made so far as is practicable, having regard to the accommodation and financial assistance available pending the erection of the new building. In this connexion an interesting stage has been reached, as five architects—selected by the board of management in consultation with their assessor from those architects who have had special experience in laboratory construction—have been invited to submit, in competition, designs for the building which is to occupy the site in Gower Street acquired some time ago for the purpose. It will be remembered that the funds for the provision of the new building and for its equipment

are being provided by the International Health Board of the Rockefeller Foundation. It is estimated that the building and site will cost well over £400,000, and that the accommodation to be provided, apart from the basement, will extend to 100,000 superficial feet of floor space. A special feature of the plans will be the large amount of space devoted to the museum. In its construction and in its equipment it is anticipated that the new school will realize the high hopes of those who have been concerned in its provision, and prove to be a worthy embodiment of the benefaction of the Rockefeller Foundation.

#### CANCER AND GOITRE.

Dr. Percy Stocks has contributed to the current number of *Biometrika* an important memoir on the statistical association of cancer mortality and the incidence of goitre. The first part of the memoir is a study of the regional distribution of cancer mortality and the estimated frequency of goitre in Switzerland, mainly based on recruiting statistics. The conclusion reached is that there is a definitely significant correlation between the rate of mortality from cancer of the stomach and oesophagus and indices of the prevalence of goitre. The less detailed statistics of other countries are next considered, and it is found that the proportional mortality of cancer of the stomach tends to be high in goitrous regions and low where goitre is infrequent. In the next place, autopsy records from the Middlesex Hospital are examined; the conclusions reached are, first, that enlargements and other anomalies of the thyroid gland are more frequent in cancer cases than in others, and that anomalies are of the types usually associated with depressed functioning of the thyroid; and, secondly, that the enlarged and adenomatous thyroid is attacked by both primary and secondary cancer more frequently than the normal gland. A preliminary study of the regional mortality from Graves's disease in England and Wales leads to the conclusion that there is a small negative association between mortality from this disease and mortality from cancer. Dr. Stocks writes: "The above findings seem to indicate that defective functioning of the thyroid gland is favourable to the incidence of cancer of the stomach, and possibly of other organs also. This leads to the suggestion that iodine prophylaxis applied after middle age, on the same lines as it is now being successfully applied to young persons in Switzerland for prevention of goitre, or some other form of thyroid administration, might result in diminishing cancer incidence. That it is at all likely to seriously influence the growth of cancer once started is not suggested, though retardation might result. It is admitted that some of the above conclusions are open to criticism, and that some of the facts might be explained in other ways, but before rejecting the hypothesis in the face of such evidence as there is, I contend that further research is called for, including, if possible, a direct experimental test of the results of prolonged iodine or thyroid administration to a cancerous strain of animals." We have quoted Dr. Stocks's words at length because there is, we think, some risk that particular sentences—for instance, the words from "The above findings" down to "incidence of cancer"—might be torn from their context and circulated among the medical profession, not perhaps constant readers of *Biometrika*, by commercial organizations whose interest in endocrine therapy is not wholly philanthropic. We are not, we hope, alone in viewing with regret the rapid extension of transatlantic publicity methods in the field of "endocrinology," and we could wish that all medical writers gave as little excuse for the broadcasting of extracts as Dr. Stocks. Dr. Stocks has, in fact, completed an excellent piece of statistical analysis.

<sup>1</sup> *Biometrika*, xvi, 1924, 364.

We see no reason whatever to distrust the arithmetical results; probably the indices of goitre are subject to much random error; this defect might decrease but could not increase the stringency of the correlations. Other factors of association—for instance, racial variations—will no doubt be considered by Dr. Stocks, to whom we wish success in the field he has now entered. The refined analysis of cancer rates is an arduous task; he who undertakes it must be prepared for many disappointments; but the task must be undertaken and must be completed, or the material will remain, what it has too often been in the past, the plaything of faddists, untrained in medicine or statistics.

#### FOOD INVESTIGATION BOARD.

THE report of the Food Investigation Board and its various committees for the year 1923<sup>1</sup> has now been issued; it reached us simultaneously with the announcement of the knighthood conferred on the chairman and director of the Board, Mr. W. B. Hardy, F.R.S. As in former reports, the introduction gives a brief account of the most important event of the year—in 1923 a scientific expedition to Australia to study the conditions of apple transport to this country—and a series of finger-posts to the main subjects dealt with in the several sections that follow. Section I, which deals in particular with the refrigerating industry, discusses the theory and practice of the freezing, chilling, and thawing of foodstuffs, more particularly beef and eggs. In Section II the physics of frozen fish and the preservative action of ice containing small quantities of some disinfectant are discussed by the Fish Preservation Committee. In Section III the Meat Committee reports the continuation of its studies in autolysis, and other investigations carried out at Cambridge in the Biochemical Laboratory and the Low Temperature Research Station. Notable among these was a series of studies on the growth of *Staphylococcus aureus* in meat extract. Among the technical matters dealt with in Section IV by the Engineering Committee is the devising of a portable apparatus for observing the ripening process in apples and pears. Section V illustrates the wide field covered by the Fruit and Vegetable Committee, ranging from the commercial storage trials into the temperature and metabolic balance in living plant tissues, through CO<sub>2</sub> production in apples and the physiology of fungal infection, as far as investigations into the cell wall substances of plants. Section VI gives an outline of the work carried on under the supervision of the Oils and Fats Committee, more especially research into the products of the hydrolysis of fats, and into the deposition of fat in yeast cells and in certain fruits and seeds. Lastly, in Section VII, the Canned Food Committee discusses the work on the chemistry of canned fish, carried out at Cambridge. The facilities of the Low Temperature Research Station made it possible to use fish whose history was exactly known from the time of catching; and, with the aid of a hand-canning machine, to complete in the laboratory the whole process of cleaning, brining, scaling, and cooking. It appears from this report that changes in the fish material occur during the first three processes, resulting in the accumulation of products of degradation, and that a marked increase of such products occurs during the cooking process, with a further small but gradual increase of volatile bases during storage of the canned fish, the last named increases being greater at higher storage temperatures.

#### INCOME TAX DEDUCTIONS.

Our readers may have noticed in a recent issue of the *Times* a letter signed "M.D.," in which it was pointed out that in the "Notes and Instructions" issued officially

with the forms of declaration of income tax the allowance of a proportion of the rent of a dwelling-house used partly for business purposes was specifically referred to in such a way as to convey to the mind of "M.D." that the allowance did not extend to a similar proportion of rates. As those of our readers who may have had occasion to peruse the answers to correspondents given in this JOURNAL from time to time are no doubt aware, this was a misunderstanding of the position, and unfortunately it appears to be one which cost "M.D." dear. The fact is, of course, that the income tax code of to-day is, in the main, founded on an old statute, that of 1842, which was conceived and drafted at a time when the country was free from the complexities of our modern industrial system. To-day the circumstances in which various incomes are derived differ so widely that no one would be likely to suggest that any particular expenses should be enumerated as allowable, in view of the obvious impossibility of making such a list inclusive; the laying down of general principles would be the method adopted; mention of specific expense would be avoided as misleading. Such principles are far to seek in the older statutes, and in so far as they do exist have to be deduced from such rules as "no sum is to be deducted in respect of any expenses not wholly and exclusively incurred for the purposes of the trade, profession, or vocation"—a rule which has probably been too strictly construed by a good many taxpayers besides "M.D." Common sense appears to suggest a redrafting on a more modern basis of the whole income tax code, but this would carry with it the disadvantage that it would necessitate discarding particular phrases and words which have been tested and defined in the High Court, and the adoption of other phraseology which might lead to a new harvest of litigation and expense. In passing, it may be remarked that recent legislation has to some extent reduced the hardship created by extending the time limit for repayments, but this remedy must remain partial, at least so long as any time limit remains in operation. The real protection, as is so often the case, lies in constant vigilance on the part of the individual. If each taxpayer will insist on a clear statement—for example, from his local inspector of taxes—of the precise reason why expenses which appear reasonable should not legally be allowed, such misunderstandings as that referred to above will become infrequent, and incidentally some good may be done by the direction of the official mind to some of the anomalies of the present tax.

#### LECTURES AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE usual courses of lectures will be given at the Royal College of Surgeons of England during January and February. Sir Arthur Keith will begin a course of six Hunterian lectures on recent discoveries of fossil man on Monday, January 19th. The lectures will be illustrated by casts and preparations from the museum and by lantern slides. The first two lectures (on January 19th and January 21st) will deal with the antiquity of man in South Africa, as illustrated by the Boskop skull and the Rhodesian skull respectively. The third lecture (on Friday, January 23rd) will be concerned with recent discoveries in Australia and Java and their bearing on the theory of man's evolution. The subject of the lecture on Monday, January 26th, will be Neanderthal man in Malta; that of the lecture on Wednesday, January 28th, will be recent discoveries of fossil man in France and Germany. The course will be brought to an end on Friday, January 30th, by a lecture on recent discoveries of fossil man in England and their bearing on the early distribution of racial types in Europe. Lectures will be given during February by Mr. Zachary Cope on extravasation of bile; by Mr. H. P. Winsbury White on hydronephrosis; by Mr. A. H. Todd

<sup>1</sup> London: H.M. Stationery Office, 1924. 3s. net.

on syphilitic arthritis; by Dr. V. E. Negus on some disorders of the larynx; by Mr. R. Jawford Knaggs on osteitis deformans; by Mr. Stanford Cado on regional anaesthesia; and by Mr. C. P. G. Wakeley on ectopic and imperfect descent of the testis. On February 18th and 20th Dr. G. Scott Williamson will give two lectures on the thyroid apparatus, and on February 23rd, 25th, and 27th Dr. G. W. de P. Nicholson will lecture on the nature of tumour formation. The lectures will be given at 5 p.m. on each day.

THE Hunterian Oration will be delivered by Sir D'Arcy Power, K.B.E., in the theatre of the Royal College of Surgeons of England, at 4 p.m. on Saturday, February 14th, the anniversary of the birth of John Hunter. It will be illustrated by lantern slides made from a series of contemporary drawings showing John Hunter the man and martyr to science. It is noteworthy that in its long history the oration has never before been given by father and son. Mr. Henry Power was Hunterian Orator in 1889.

A SMALL unit for the reception of in-patients unable to pay ordinary fees was opened at the London Radium Institute, Riding House Street, on January 5th. It consists of two wards on the cubicle system, one containing four beds for women and the other three for men, together with a properly appointed operating room for use in cases in which the surgeon must prepare the way for the application of radium. Patients will be expected to contribute as much as they can afford to the cost of maintenance, and to ensure that this is done an almoner will be appointed. Patients must be recommended by their medical attendants, who will be asked to certify that the disease is of a kind likely to be benefited by treatment. For the last two years seven beds have been available for paying patients.

## THE BICENTENARY OF GUY'S HOSPITAL.

### COMMEMORATION SERVICE.

A SOLEMN service in commemoration of the founder and other benefactors of Guy's Hospital was held at the neighbouring cathedral church of St. Saviour, Southwark, on January 6th. The day marked the bicentenary of the opening of the hospital "at the sole costs and charges of Thomas Guy, Esquire," the City bookseller, who died on December 27th, 1724, ten days before the cherished project of his old age reached fulfilment.

The Prince of Wales, president of the hospital, was received by the treasurer of the hospital and by the Bishop of Southwark, acting as dean of the cathedral, and was conducted to a dais just below the pulpit. In addition to the Bishop of the diocese, the Bishops of Oxford and Woolwich and Bishop Talbot walked in the procession of clergy. The cathedral, whose interior is one of the most cheerful and best lighted in England, presented a striking picture when the congregation was seated, the academic gowns in all parts of the nave and the nurses' uniforms in the transepts contributing to the effect.

The prayers, which were said by the hospital chaplain (Canon J. B. Haldane), included the collect of St. Luke and petitions for the doctors and nurses, for the patients, and for past members of the hospital staff. The lesson, read by the Bishop of Southwark, was from Ecclesiasticus xxxviii, the passage beginning, "Honour a physician with the honour due unto him for the uses which ye may have of him." The anthem, "The spirit of the Lord is upon me," was finely rendered by a full choir.

The Bishop of Oxford, who preached the sermon, said that it was fitting that that company should gather in the cathedral church, which was linked by ties new and old with the hospital of Thomas Guy, to offer its tribute for the service which, during the last two hundred years, the hospital had rendered to "the least of Christ's brethren."

It was fitting also to return thanks for the opportunity of simple Christian service which was called forth by the bounty of Guy, and which had enabled this work to grow and to gain so signal a place in national life and tradition. Guy's Hospital represented one instance—conspicuous enough, but still only one instance—of that single-minded Christian service with which our history was so rich. The Bishop went on briefly to sketch the career of Thomas Guy, the one-time apprentice lad, who, by his industry and intelligence, accumulated a great fortune and devoted it to serving his fellow men in various philanthropies, of which his hospital was the culmination. Guy laid well and truly the hospital foundations, and in each succeeding generation, as new needs had arisen, new men had come forward to take the place of those who had gone before. To-day the name of the bookseller was linked with a noble line of men, leaders in medicine and surgery in each generation. The Bishop mentioned James Jurin, William Saunders, Benjamin Guy Babington, Thomas Bright, Richard Bright, Walter Moxon, Charles Hilton Fagge, Sir William Gull, George Owen Rees, Golding-Bird, Samuel Sharp, Astley Cooper, Charles Aston Key, and James Hinton. All of these in their turn honoured the founder of the hospital and recognized the debt which medical science owed to his benevolence and far-sightedness. It could not be doubted that the future historian of this present time would find in it two distinguishing features. One of these would be the wonderful development of scientific knowledge applied to the treatment and cure of disease, the alleviation of human suffering, the saving of human life, the skilful nursing of the sick, and, not least, the careful training of young students in the great medical schools. All honour to the physicians and surgeons and nurses for the use they had made of their God-given talent. It would be a sorry day if the large-hearted generous spirit of Thomas Guy were stifled in the fever and fret of modern England. Earlier in his sermon the Bishop had deprecated the suggestion that the provision for the needs and development of hospitals should be by a compulsory tax. What Christ claimed was the free and willing service for "the least of these my brethren" on the part of those who bore His name. The other distinguishing feature of our generation would be regarded by a later day as the accumulation of great wealth. Fortunes which, in his own boyhood, were regarded as quite exceptional were now frequently made by business men. It was easy enough to take Guy's Hospital as a matter of course, and not to see that it stood for something in our common life which we could ill afford to be without. There, amidst the throngs and thoroughfares of crowded, pitiless London, where the individual might easily be led to believe that he could count for nothing, this hospital stood while the generations came and went, and it bore witness to those simplest, deepest truths which God would have all his children learn and teach, that human life was a sacred thing, that the highest duty was always possible, that self-sacrifice was sweet, and that the service of one's fellow men was the crown of being.

Among those present in the congregation were the treasurer of the hospital, Mr. F. P. Whitbread; the Hon. Evelyn Hubbard, Lord Revelstoke, and other governors; Mr. H. L. Eason, C.B., C.M.G., superintendent; Sir Arbutnot Lane, Sir Charles Symonds, Mr. C. H. Golding-Bird, Dr. John Fawcett, Sir Alfred Fripp, and other members of the medical and surgical staff; Miss Margaret Hogg, the matron, five former matrons of Guy's and members of the present nursing service; the deans of Guy's and of other London medical schools; Sir Humphry Rolleston, P.R.C.P., Sir John Bland-Sutton, P.R.C.S., and Mr. A. D. Brenchley, Master of the Society of Apothecaries; the Vice-Chancellor (Dr. E. A. Gardner) and other representatives of the University of London; Lord Stuart of Wortley, Sir Francis Champneys, and other representatives of King Edward's Hospital Fund; Sir W. J. Collins, representing the League of Mercy.

Although it was not mentioned at the service, the bicentenary celebration corresponds with the issue of a financial appeal on behalf of the hospital. A resolution, approved by the Prince of Wales, has been passed by the Court of Governors to the effect that an attempt should be made this year to relieve the hospital and medical school of their burden of debt by the provision of £160,000 for the former and £40,000 for the latter. The total is not quite equal to the original endowment (£220,124 2s. 7½d.) which Guy's received from the fortune of its founder.

## THE MEDICAL RESEARCH COUNCIL.

## ANNUAL REPORT.

THE annual report of the Medical Research Council for the year ended September 30th, 1924, contains a review of the tenth completed year of the work of the Council and its predecessor, the Medical Research Committee. It is an octavo volume<sup>1</sup> of 142 pages, and is provided with indexes of personal names, of institutions, and of subjects, as well as a table of contents. Cross-references also are introduced in the text; whoever subedited the volume for press deserves a word of praise.

As already announced, the Earl of Balfour has, since the completion of the Council's year, become its chairman in succession to the Right Hon. Edward Wood, and the Right Hon. William Graham, M.P., and Professor E. P. Cathcart, F.R.S., of Glasgow, have succeeded Mr. A. G. Church, M.P., and Professor Noël Paton as members of the Council.

We cannot pretend to follow the report page by page; many of the sections, indeed, do little more than enumerate the researches promoted or subsidized by the Council, together with the names of workers and lists of papers published. Even so they produce a strong impression of the number and diversity of the subjects, nearly all of them more or less closely related to clinical medicine, that are being attacked. We shall here direct attention to only a few the study of which has been advanced, a distinct stage. The Council has continued the policy of working in close co-operation with university departments and schools of medicine, and with other research institutions, among which special mention is made of the Lister Institute. In this way the universities and institutions are helped, and the funds at the disposal of the Council expended in the most economical manner. The report contains a long list of the special committees by which the expenditure is guided, and the researches in progress supervised.

## NATIONAL INSTITUTE FOR MEDICAL RESEARCH.

At the National Institute for Medical Research at Hampstead, maintained directly by the Council, the chemical laboratory has been reconstructed and the facilities for chemical manipulation greatly increased. The site acquired at Mill Hill for a field laboratory associated with the Institute has been developed, and the greater part of the buildings have been completed and are in use. Special buildings for the research into canine distemper have been erected as an addition to the Council's own laboratory accommodation there. The Field Distemper Council has provided from the voluntary subscriptions it has received the cost of the kennels and other necessary buildings in an isolated compound for the purpose of breeding a stock of dogs which shall be free from chance infection, and has provided also separate accommodation for the experimental animals and controls at a later stage. Workers are subject to rigorous discipline as to bathing and changing of clothes in the cleansing house, which provides the only means of entry and egress. The investigation of the virus of distemper has been undertaken by Dr. W. E. Gyo and Dr. P. P. Laidlaw, working at the Field laboratories; they have the co-operation of the workers at the National Institute at Hampstead, including Mr. J. E. Barnard, F.R.S., and Mr. C. Dobell, F.R.S. The disease will also be studied from other points of view as opportunity offers. A bacteriological and pathological examination of a series of infected dogs from an external source has already been made by Mr. R. E. Glover, who is now working with Professor J. B. Buxton in the Department of Animal Pathology, Cambridge.

The scheme of Rockefeller medical fellowships, tenable in America by scientific workers in the British Isles, mentioned in the last annual report, is now in working order. The first four Fellows, who went to America during the academic year 1923-24, have now returned; they have been replaced in America by six others.

## INSULIN.

Much was done during the year towards simplifying the manufacture of insulin, and so by lowering its price making it more generally available, and progress has also been made in the study of its nature and mode of action. Dr. H. W. Dudley and Mr. W. W. Starling, working at the National Institute, found a laboratory method of improving the yield and the purity and a better way of recovering insulin, as a chloride, in the picric acid process. Dr. Dudley has also utilized the solubility of insulin picrate in mixtures of alcohol or acetone with water for the preservation with picric acid of islet tissue, found in certain common food fishes (including cod), and the subsequent extraction of insulin. Drs. Dodd and Dickens, of the department of pathological chemistry of the Middlesex Hospital, having independently observed these special solubility relations of insulin picrate, applied a similar process to the mammalian pancreas, and obtained some very high yields of insulin. Light has been thrown by Dr. Burr and Dr. H. H. Dale, F.R.S., director of the department of biochemistry and pharmacology of the National Institute, on the still obscure question of how sugar is removed from the circulating blood. As the result of experiment they conclude that the murexes are the chief agents, and that, provided the supply of sugar is maintained, the process is accompanied by increased oxidation. All the sugar that disappears cannot be accounted for by this combustion; where the rest of the sugar is stored, and in what form, has not yet been ascertained.

The sensitiveness to insulin of animals of the same species is known to vary within wide limits. Dr. Burr and Mr. Marks have shown reason to believe that this is related to variation in the activity of the thyroid gland. The apparent antagonism between these two hormones has led to the trial of insulin in exophthalmic goitre with promising results, as narrated in the preliminary report by Dr. R. D. Lawrence, published in our columns on October 25th, 1924 (p. 753).

Five firms, two of them in combination, are now engaged in the manufacture and distribution of insulin; the combined output exceeds an average of a million units a week, and permits the export of large quantities to other parts of the empire and to foreign countries. The Council has entered into agreements with each firm for the supply of scientific information and for the close control of the quality and the price of the products sold. Owing to improvements and simplifications introduced as a result of the laboratory experiments the price of insulin has been reduced on several occasions and is now one-tenth of that originally found necessary, and considerably lower than the corresponding price in America. An essential part in the manufacture in this country is taken by the picrate method of purification already mentioned. Patent rights in this process were acquired by the Council for its protection against exploitation during the stages before publication; at the request of the University of Toronto these rights were extended to Canada and the United States and have been offered to the University to be exercised without charge for royalties in the same manner as the Council here exercises the rights assigned in the original insulin process. Insulin has recently been made available in the alternative form of sterile tablets. At the International Conference of Biological Standards in Edinburgh in July, 1923, the standards department of the National Institute of Medical Research accepted the duty of preparing a dry, staple standard of insulin. The work is now practically complete, and a trial sample has been submitted to the Toronto Insulin Committee, with a view to agreement on the exact form in which the mixed standard preparation shall be distributed. The routine control of the potency and sterility of all insulin issued for sale in this country is carried out in the Institute, and the methods of assay have been improved.

<sup>1</sup> 1924. H.M. Stationery Office or through any bookseller. Price 1s. 6d. net.

## FILTERABLE VIRUSES.

A good deal of work was done during the year with regard to the filterable viruses the existence of which has been proved or is suspected, but the results obtained do not lend themselves to summarization. The technical methods which must be employed are troublesome, and a sort of watchful scepticism must be continuously exercised. As an example it may be noted that Dr. P. P. Laidlaw spent much time at the National Institute in the study of certain appearances which developed in culture tubes of solid media inoculated with filterable viruses; they mimicked colonies of living organisms, but proved to be inanimate collections which could be produced in equal abundance from sterile implantations. The observation is of value in clearing up errors in previous work and for preventing their repetition. An investigation started at the field laboratories, Mill Hill, by Dr. W. E. Gye on the filter-passing virus of Rous chicken sarcoma is giving results which are described as very promising. Mr. J. E. Barnard, F.R.S., honorary director of the department of applied optics of the National Institute, has made progress with a method of using ultra-violet light for the microscopic study of particulate bodies smaller than those visible by ordinary light. An illuminator is now also being made on a new principle to enable bodies within the limits of visibility to be photographed in ultra-violet light without readjustment of any of the optical parts. The principle has already been applied to the smallest organism available, the virus of bovine pleuropneumonia, which has been photographed in ultra-violet light while in the living state and at various stages of its development. If and when filterable viruses are cultivated the method, it is anticipated, will be applicable to them.

Dr. Mervyn Gordon, F.R.S., is continuing at St. Bartholomew's Hospital his investigations of the filterable virus of vaccinia. A method of killing it has been found and the immunizing value of the same virus alive and killed compared. Protection is given by the killed virus, and its degree and duration are being studied. The prevalence of small-pox in this country has afforded an opportunity of comparing the virus of variola with that of vaccinia. In Dr. Gordon's laboratory Dr. T. G. M. Hine is engaged in the study of the growth of filterable viruses in association with tissue cultures. Dr. P. W. Twort, who is continuing his experiments on the cultivation of vaccinia virus, has also investigated the bacterial lysis; no definite filter-passing substance has been obtained for this group of micro-organisms such as has been found associated with the micrococci group and the dysentery-typhoid-coli group.

Inquiries have also been prosecuted into the pathology of lethargic encephalitis and its alleged relation to febrile herpes. Dr. Perdrau of the Lambeth Infirmary, who has been freed to give up most of his time to these problems, has continued to work with Dr. Laidlaw at the National Institute on filterable viruses and especially that of herpes. He paid a visit to Sheffield during the epidemic of lethargic encephalitis there in April last, and by the courtesy of Professor A. Hall and Professor J. S. C. Douglas was enabled to study the possibility of transmitting the disease. A fatal though mild encephalitis was produced in rabbits, but attempts at further transmission failed; a similar disease could be produced in rabbits, partially immunized, by inoculating the virus of herpes. It was found also that a mild form of keratitis, sometimes followed by partial immunization against the virus of herpes, could be produced "in a notable proportion" of cases infected with the nasal washings of patients suffering from lethargic encephalitis, but further transmission was not achieved. Dr. J. E. McCartney, continuing work done last year at the Rockefeller Institute, New York, has ascertained, while working in the University of Edinburgh, additional facts as to the biology of the virus, and has found it possible to extend the duration of its viability in artificial media, but not to prove its multiplication outside the body. Attempts to transmit the disease from human beings to rabbits failed.

## LIGHT.

During the year the investigation of the biological actions of light has occupied much of the attention of the department of applied physiology of the National Institute. The members of the staff, Dr. Leonard Hill, F.R.S.

(Director), and Dr. Agell Campbell, have studied local actions of light on the body, using the production of stasis in the capillaries of the mesentery as an indicator. The efficiency of different artificial sources of light has been studied by Drs. Hill and Eidinow and Mr. Angus. The spectrographic study of lamps has been aided by Mr. Barnard and Mr. Smiles; the conclusion is that "long-flame" arcs are more efficient than the short-flame Finsen lights hitherto used in phototherapy. Details of the results obtained are to be published shortly.

Daily measures are taken of the values of the ultra-violet rays at Hampstead, in the smoke-polluted centre of London, and in the open country in Oxfordshire, at Harrogate, and at the Liverpool Sanatorium, Cheshire. Readings are also being secured to illustrate seaside, alpine, arctic, and tropical conditions. The method will provide a ready means of measuring in medical practice the dosage of ultra-violet rays given by lamps. Mr. Angus, at the National Institute, has, by a modification of the apparatus, found that more of the ultra-violet rays, even on sunny days, came from the sky as a whole than direct from the sun. This is particularly true when the sun is low or obscured by cloud—a fact of practical importance in heliotherapy. The actions of light in the treatment of chronic inflammatory diseases have been observed in patients suffering from surgical tuberculosis and chronic dermatitis, lupus vulgaris, anaemia and high blood pressure, and asthuma. A lamp has been installed at the New End Hospital, and the London County Council has placed six beds there at the disposal of Dr. Hill for light treatment of chronic severe cases of surgical tuberculosis. Drs. Colebrook, Eidinow, and Hill have found that exposure of the skin to ultra-violet radiation leads to an increased bactericidal power of the blood and serum; so, also, do heat rays and mustard poultices. Dr. Eidinow has found that exposure of defibrinated blood to ultra-violet radiations destroys its bactericidal power, but that if this irradiated blood is passed into the circulation an increase in bactericidal power is observed. We mentioned some time ago that Miss E. M. Hume and Miss Henderson Smith had observed that normal growth can be induced for a time in rats fed on a diet deficient only in fat-soluble vitamin if the animals are irradiated with the mercury-vapour quartz lamp, and that this effect can be produced without exposing the rat directly to the source of light. This observation was not confirmed by others. It now appears that the effect is not obtained unless wood sawdust (or possibly other bodies not yet investigated) is present in the jar at the time of irradiation and afterwards. The nature of this curious phenomenon is being further explored.

(To be continued.)

## ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee thirty-seven cases were considered and £547 10s. voted to thirty-four applicants. The following is a summary of the new cases relieved.

M.R.C.S. Eng. 1896, aged 55, now unable to work owing to paralysis. He and his wife are living on the charity of friends. His wife has to look after the applicant. Voted £26 in twelve instalments.

M.D. Cantab., aged 71, is unable to regain his practice after the war and now owing to old age and infirmities can scarcely walk. Applicant's health necessitates his wife's constant attention. They are now dependent on friends. Voted £26 in twelve instalments and £10.

The widow, aged 59, of M.B. Glas., who died in 1899. The applicant received £8 from maternity nursing, but has been unable to work since August owing to trouble with her eyes. She sublets one room for £12 a year; her rent and rates amount to £27 per annum. Voted £10.

The widow, aged 57, of L.S.A. Lond., who died in 1923. Through illness she has had to give up her post as companion and is now entirely dependent on her daughter, who earns 5s. a week. Voted £10.

Daughters of M.R.C.S. Eng. who died in 1912. Their ages are 56 and 47. The elder nursed her father, who was paralysed for twenty-two years, and is not at all strong. The younger sister is a daily governess at £50 a year. They receive help from their brother and brother-in-law. Voted £18 in twelve instalments and £12 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir

Charters Symonds, K.B.E., at 11, Chandos Street, Cavendish

Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives

many applications for clothing, especially for coats and

skirts for ladies and girls holding secretarial posts, and

suits for working boys. The Guild appeals for second-

hand clothes and household articles. The gifts should be

sent to the Secretary of the Guild, 58, Great Marlborough

Street, W.1.

## Scotland.

### EDINBURGH ROYAL INFIRMARY.

THE annual report of the Royal Infirmary, Edinburgh, for the year ended September 30th, 1924, describes certain extensions which are in progress, and indicates the necessity for several important developments required in the near future.

#### Ear, Nose, and Throat Department.

The ear, nose, and throat department had for some time been found inadequate in size to cope with the large list of patients waiting admission to the wards for treatment. This waiting list during the past year formed about 44 per cent. of all the patients awaiting admission to the institution. It was decided, therefore, to add two new theatres, with sterilizing rooms and other accessories, two new examination rooms, and two extra wards with accommodation for twelve beds in each. The scheme was considerably delayed by the dispute in the building trade, but the work is now well under way, and it is estimated that these additions, which will cost some £17,000, will be ready during the course of the present year.

#### Radiological Department.

The new radiological department, which is estimated, with buildings and equipment, to cost £52,000, was described in our issue of December 27th, 1924 (p. 1213). Work has already been commenced in preparing the ground for this department, and it is hoped that it will be ready for use by October next.

#### Proposed New Maternity Hospital.

The question of providing a new maternity hospital is intimately associated with the interests of the Royal Infirmary, and it is now regarded as imperative that the institutions should be at least near together and in close co-operation with each other. The arrangements recently made between the Royal Infirmary and the Merchant Company with regard to the acquisition of the ground occupied by George Watson's School were mentioned in our issue of December 6th, 1924 (p. 1075). When these have been completed it is expected that part of the site will be available for a new scheme connected with the Royal Maternity Hospital.

#### Clinical Research Laboratory.

The Rockefeller Foundation of New York intimated some time ago to the Edinburgh University Court its readiness to make a grant of £35,000 for the building and equipment of a laboratory for clinical research, on condition that it was accommodated within the grounds of the Royal Infirmary. After negotiations between the University and the managers of the Royal Infirmary, it was agreed that the Infirmary would permit the erection of this laboratory on condition that, when erected, the building should become the property of the hospital. The managers of the Infirmary are satisfied that the scientific research which will be carried out in this department should make an important addition to the benefits derived by patients from the hospital, which are the board's primary interest and concern.

#### Social Service Organization.

A social service scheme has been gradually developing since permission was given in 1923 to the University Settlement (School of Social Service) to carry out through their lady visitors social service work among the out-patients of the Infirmary. This work has consisted in following up necessitous cases at their homes, providing them with the drugs or special nourishment they needed, arranging for their admission to convalescent and other homes as required, and improving from a health point of view their surroundings in their homes. This scheme forms a complement to the work done for patients in the wards of the hospital by the Samaritan Society, and it has been greatly appreciated by the members of the honorary staff. It has involved the appointment of a lady almoner and a staff of assistants, and entails an annual expenditure of £500 or thereabouts.

The scheme actually brings about a great saving in expenditure, since it permits of the treatment as out-patients of patients who otherwise would have to be accommodated in the wards, and it tends to shorten the stay in hospital of certain classes of case, and to do away with the necessity for return to hospital of many patients who have already received in-patient treatment.

#### Number of Patients Treated.

The number of patients treated during the year was 15,687; this was an increase of 644 upon the figure for the previous year. The average daily number of patients in hospital was 903, the highest number of patients in one day being 940, and the average length of stay of each patient under treatment was 20.68 days, as against 21.3 days in the previous year. The percentage of deaths among cases treated was 6.1, but deducting the deaths which occurred within forty-eight hours after admission the percentage was 4.5, or 0.3 per cent. less than in the preceding year. The number of individuals treated as out-patients was 48,349, an increase of 2,746 over the number treated in the preceding year. An indication of the pressure on accommodation within the hospital is afforded by the fact that there was during the year an average waiting list of 1,812, of which, however, 794 were accounted for by the waiting list of the ear, nose, and throat department for minor operations.

#### Finance.

The total ordinary income was £107,907, including £70,416 derived from fortnightly contributions, the latter showing an increase of over £1,694, as compared with the preceding year. An important source of revenue is the Badge Day Collection Scheme in town and country, by which £6,071 was raised in the past year, being an increase of £1,377 on the revenue from the same source in the previous year. A still more important source of revenue, which shows a tendency to steady increase, is found in the League of Subscribers, which includes employees in public works, business establishments, staffs of schools, Government and other offices, etc. From this source £20,904 has accrued in the past year. The contributions from some of the groups comprised in this League have diminished owing to unemployment and other causes, but this has been more than counterbalanced by increase in other places and from other groups of employees, so that from this source the amount of contributions shows an increase of £557 over that for the same source in the previous year. It is computed that the number of individuals subscribing to the support of the institution through this League on a systematic basis of not less than one penny a week is now 96,500, distributed over 1,373 groups. The massed contributions from miners engaged in the coal and shale industries, chiefly in the Lothians and Fifeshire, amounted to £14,669. The ordinary expenditure was £127,536, being an increase of £7,726 on that of the previous year. A considerable part of this was due to rise in the price of provisions, such as meat, eggs, milk, and especially potatoes. The extraordinary income amounted to £74,719, while the extraordinary expenditure was only £6,576. The cost per bed was £141 4s. 9d., an increase of £7 13s. 5d. on that for the previous year, but it is claimed that this annual rate of expenditure is considerably lower than that of the majority of the hospitals of similar size and nature in other parts of the British Isles.

#### MEMORIAL TO SIR WILLIAM MACWEN.

\* At the conclusion of the meeting of the managers of the Glasgow Royal Infirmary on January 1st a medallion memorial tablet to the late Sir William Macwen was unveiled by Professor W. K. Hunter. The memorial is placed in the central hall of the Dick surgical block; the design, by Mr. Proudfoot, is similar to that of the Lord Lister memorial in the same hall. It consists of a bronze medallion in a marble setting, and bears the following inscription in gold:

"Sir William Macwen, C.B., M.D., D.S., LL.D., F.R.S., Regius Professor of Surgery in the University of Glasgow, Surgeon to this Infirmary from 1877 to 1892. Erected by the past and present members of the visiting staff, 1924."

## Ireland.

### SIR JOHN CAMPBELL, M.D.

It was with wide and general satisfaction that not only the medical profession but also the public in Northern Ireland saw the inclusion of Dr. Campbell's name in the New Year's honours list; it is considered as due not so much perhaps to his eminent public services as to his long, faithful, and distinguished purely professional work: the profession feels it as an honour to itself. Sir John Campbell is the son of the late Rev. Robert Campbell, minister of the old Presbyterian Church at Templepatrick, County Antrim; he is the elder brother of the late Mr. Robert Campbell, who did so much for general surgery in Northern Ireland, and to whose memory the profession founded the Robert Campbell Memorial Oration. Sir John Campbell was educated at the Royal Academical Institution, Belfast, and took the B.A. and M.A. degrees in the now extinct Queen's University, with first class honours; he graduated M.D. in 1887, and became F.R.C.S. Eng. in 1891. After graduation he studied in London, Paris, and Vienna, and was demonstrator in anatomy in the Queen's College for five years under the late Professor Redfern. He specialized in gynaecology and obstetrics, and was appointed to the Samaritan Hospital for Women, Belfast, of which he is now senior surgeon, and to the Maternity Hospital. He was chairman of the Queen's University Veterans' Volunteer Corps, and in 1916 he served as surgeon to the British Red Cross Hospital (No. 5) at Wimereux for six months while some of the heaviest fighting was going on. He has been president of the Ulster Medical Society and of the Ulster Branch of the British Medical Association. He succeeded the Right Hon. Thomas Sinclair, M.A., as chairman of Convocation of the Queen's University, and in 1921 was elected M.P. for the University in the Parliament of Northern Ireland. His contributions to the literature of his specialty are many and varied. The profession in Northern Ireland and his numerous friends will join heartily in offering Sir John and Lady Campbell their warm congratulations and their wishes for long life and health to enjoy the well deserved honour.

### FERMANAGH COUNTY HOSPITAL.

At the last meeting of the Fermanagh County Council a deputation from the committee of management of the county hospital attended and suggested, amongst other matters, that the various district hospitals in the county should be closed, and the county hospital enlarged from 54 to 85 beds. The deputation stated that enlightened opinion is agreed that it is wasteful and extravagant for a small community to maintain three inefficient hospitals, the county hospital being inefficient on account of its small size, the two union hospitals inefficient to such an extent on account of their defective construction and want of equipment that their more serious cases have to be sent to Dublin, Belfast, or to the county hospital, with which last all three rural district councils have an agreement to take such cases on payment. The committee of the county hospital thinks, and the members of the profession agree, that a lying-in ward with convalescent rooms off it would be a boon to the public. In this section any medical practitioner in the county could arrange to attend his own patient. The special accommodation provided for the nurses and servants will leave a number of rooms available as private or semi-private rooms; they will, in effect, provide a small nursing home for the county, in which private or paying patients would have the advantage of being attended by the medical man of their own choice in certain cases. The charge for private wards would be, say, £4 4s. a week, and for a semi-private room—that is, with one other patient—say, £3 3s. a week (as in any other nursing home, stimulants, medicines, and surgical dressings would be extras). This would provide a service that would compare favourably with that of any nursing home in Dublin or Belfast, for which a minimum charge of £7 7s. is made. These low charges of £4 4s. and £3 3s. are suggested because the hospital is not a dividend-earning

concern. They would, however, represent a reasonable profit to the hospital and be a source of revenue to meet other expenses.

### WHOLE-TIME MEDICAL REFEREES.

The National Health Insurance Commission has decided to make three whole-time temporary appointments of district medical referees for the Free State. The candidates must be registered medical practitioners, with a knowledge of general practice, and not over 45 years of age. The salary offered is at the rate of £600 a year, without bonus, together with travelling and subsistence allowances. A preference will be given to candidates who have served in the National Army Medical Service. The latest day for receiving applications will be January 12th. The appointments will be made by means of a selection board set up by the Civil Service Commission. In connexion with these appointments the medical representatives of the Irish Medical Committee attended a conference with the Irish Insurance Commission and pointed out that the salary offered was altogether inadequate and was not calculated to secure such experienced medical practitioners as would command the confidence and co-operation of the profession. The Commissioners ultimately agreed to offer £700 a year, and stated that their funds did not permit them to offer a higher salary. In the face of this agreement with the representatives of the medical profession it has caused much disappointment that the posts have now been advertised at a salary of £600 per annum. This has been done without acquainting the representatives of the profession that the arrangements made with the Insurance Commission were altered subsequently to the date of the conference. Such treatment will not improve the relations between the Insurance Commission and the medical profession in the Free State. Another matter that was not mentioned at the conference was the preferential treatment of certain candidates.

## England and Wales.

### YORK COUNTY HOSPITAL.

SINCE its foundation in 1741 the wards of the York County Hospital have been distinguished by numbers, with the exception of the "Victoria" ward. On December 31st four wards exchanged their numbers for names commemorating four distinguished York medical practitioners—two of the eighteenth and two of the nineteenth century. The wards were formally named by three members of the present honorary medical staff. Dr. W. A. Evelyn, naming No. 6 ward the "Burton" ward, reminded the audience that Dr. John Burton, who went to York in 1735, co-operated with Lady Betty Hastings in starting the County Hospital. A man of strong political views, he wrote on the history of monasticism in Yorkshire, and was undoubtedly the original of Dr. Slop in *Tristram Shandy*,\* by Laurence Sterne, nephew of Jacques Sterne, LL.D., against whom Burton had written an article. Dr. Evelyn named one division of No. 7 ward as the "Drake" ward, in memory of Dr. Drake, the first surgeon to the hospital, who received this appointment in 1756. In common with his colleague, Dr. Burton, he was renowned for his archaeological work in connexion with the city of York. Mr. Wilfrid Gostling, naming the other division of No. 7 ward after Mr. W. H. Jalland, whom he had known personally for more than twenty years, spoke of the great help Mr. Jalland had given in bringing the hospital up to date, referring especially to the "Victoria" ward, the balconies, the nurses' home, and the rebuilding of the operating theatre. Dr. Peter Macdonald then named ward 10, or the eye ward, after Dr. Tempest Anderson, who became surgeon to the York Eye Institution in 1876. This institution was amalgamated with the York County Hospital in 1877, and Dr. Anderson continued to be surgeon until 1904. Dr. Anderson was closely associated also with the York Philosophical Society, the museum, and St. Mary's Abbey.

\* See BRITISH MEDICAL JOURNAL, April 5th, 1924, p. 649; May 3rd, p. 799; and May 17th, p. 888.

Mrs. Seebohm Rowntree, formerly a sister in the hospital, alluded to the unselfish work of the honorary medical staff, and pointed out that the workpeople's hospital fund was originated by her husband at the time of their marriage.

#### CENTENARY OF BRADFORD ROYAL INFIRMARY.

The centenary of Bradford Royal Infirmary occurs this year, and it is hoped to celebrate the occasion by raising a large portion of the sum required for the erection of a new infirmary on the site acquired at Daisy Hill. The scheme was begun before the war, and the subscriptions promised amounted to £78,000. From the amount actually received £40,000 remains over after defraying the cost of purchasing the site and adapting a residence on the estate for the use of a nurses' home. The pre-war estimate for the new infirmary was £250,000, but it is not expected that the scheme can be completed for much less than £500,000. It is hoped that £400,000 may be received from the centenary appeal. The receipt of an anonymous donation of £30,000 towards the building of the new infirmary was reported in our issue of February 16th, 1924 (p. 291).

#### NEW NURSES' HOME OF THE LIVERPOOL ROYAL INFIRMARY.

The first wing of the new nurses' home of the Royal Infirmary, Liverpool, was opened on December 30th by Miss E. M. Cummins, to whom, during the proceedings, testimonials were presented in recognition of her fourteen years of work as matron. The completed wing was built at a cost of over £40,000, and represents one-third of the whole building. A public appeal is to be made shortly for the £30,000 required for the second portion. Dr. T. R. Glynn, who presided, remarked that the old nurses' home, which was built in 1865, was the first institution of its kind in Great Britain. The new home, when completed, would accommodate 150 nurses, and would be the largest in the country. Mr. W. Thelwall Thomas, senior member of the honorary medical staff, drew attention to the great advances made in the infirmary since Miss Cummins was appointed thirty years ago. During this period the number of surgical cases had increased very greatly, and there were more than four times as many operations, which involved very heavy work for the nursing staff.

## Correspondence.

#### INDIGENOUS MEDICINE IN MADRAS.

SIR,—In continuation of my letter which you kindly published in the *BRITISH MEDICAL JOURNAL* of October 25th, 1924, I find in the *Madras Weekly Mail*, just to hand, that "H.E. the Governor opened on November 24th a School of Indian Medicine, the first of its kind sanctioned by the Government of Madras." It is clear from this that the Madras Government has disregarded the advice tendered to it by responsible medical opinion, and has persisted in carrying out its most regrettable and retrograde policy.

There are several points in the *Madras Mail's* article to which I particularly wish to draw attention. "H.E. the Governor, who was attended by his surgeon, Major D. P. H. Johnstone, R.A.M.C., was received by the Hon. the Rajah of Panagal." I have no wish to make the position of His Excellency's surgeon more difficult than it already is, and I recognize how difficult it must be for any medical man at the present moment, but the significant fact of this officer's official presence at such a ceremony shows how necessary was the warning I gave in my letter, above referred to, of the consequences that might threaten any officer who joins such a Government as that of Madras. I would specially invite attention to the fact that not a single European officer in the I.M.S. and no other officer of the R.A.M.C. was present. Moreover, with one exception, the Indian officers of the I.M.S. appear to have absented themselves in a body from the function. This latter is a satisfactory and very significant fact.

The Minister, in his statement, gave the history of the inception of this new institution, and, in speaking of the proceedings of the committee set up to go into the matter, added: "These findings were referred to two senior I.M.S. officers for scientific criticisms, and and they would not accept

the conclusions arrived at. . . . (The italics are my own.) It is not in the least strange that they should have refused to accept the conclusions arrived at. No one who wades through this hopelessly illogical and childish report could for one moment understand them adopting any other attitude. The whole thing is an abnegation of scientific medicine, and an attempt to substitute effete and worn-out rubbish in its stead.

The Governor in his speech regretted that his Government was limited in what it could do for the health of the people (not due to any want of sympathy for them—but due to financial stringency). We have here the unedifying spectacle of a civilized government at the end of the first quarter of the twentieth century cutting down what it would admittedly like to do for the health of the people, whilst throwing away a comparatively large sum of money on a futile substitute for a system of medicine.

I trust, Sir, that this is a matter that is going to have the earliest consideration of the British Medical Association. There is, to my mind, only one course open to us, and that is to hang, bar, and lock the door against the entry of self-respecting British medical men into the service of a Government that can behave so foolishly and so perversely as this.

There is one hopeful feature in the whole situation. I have received a message through an absolutely reliable channel from a number of young medical graduates of the Madras University saying that "they hope it will not be inferred from my letter that the average graduate from the Madras School has sympathy with or leanings towards the Ayurvedic system." They assured my correspondent that "they would be very sorry to be classified with the few who are so disloyal to their teaching." My correspondent goes on to say: "Possibly your letter might give an impression that the bulk of our Western system men out here were not wholeheartedly of their teacher's views. I think that that would be a pity. I have promised them to write to you on the subject." On re-reading my letter I cannot find that there was any such imputation, though I must confess that I was not sure what the real feeling among the younger Indian medical men was. I am glad to give prominence to their views, which are in happy contrast to the action of their rulers.

It is only fair to add that I have received an assurance that H.E. the Governor did not expect I.M.S. men to attend the opening of this self-styled school. It is impossible to believe that intelligent men, whether Europeans or Indians, can have any real sympathy with such movements as this, but it is none the less lamentable that in response to unreasonable clamour a British Government should lend its authority to such a movement.—I am, etc.,

London, W.1, Jan. 2nd.

R. H. ELLIOT, M.D.,  
Lieut.-Colonel I.M.S. (ret.).

#### ACCLIMATIZATION TO HIGH ALTITUDES.

SIR,—So far as the thyroid gland may be concerned in acclimatization to high altitudes the facts now known are these:

1. With increasing altitudes up to 6,000 feet the organ tends to assume a more active state of secretion, which is, however, within the normal range of the gland's physiological action in the absence of excitants of abnormal activity. Thus, at altitudes of 750 feet above sea-level in India 50 per cent. of the thyroids of normal wild rats are in the colloid or resting phase of secretion and 50 per cent. are in the phase of active secretion. At altitudes of 6,000 feet in the Himalayas as many as 82 per cent. may be in the latter phase, while of these 20.9 per cent. show an almost complete absence of colloid. These changes, however, are not associated with any increase in size of the gland.

2. Diminished oxygen supply, such as may be induced by experimental stenosis of the trachea or by confining animals in an atmosphere deficient in oxygen, causing a depletion of the gland's store of storable colloid, and, therefore, of its iodine content.

3. Experimental hyperthyroidism in rats, induced by thyroid feeding, renders these animals hypersensitive to diminished oxygen supply.

4. With increasing altitudes the iodine content of the air falls, and snow water is deficient in this element.

There are, so far as I am aware, no observations in regard to the effect of altitude on the gland at heights above 6,000 feet, but certain symptoms from which members of the Mount Everest expedition suffered—loss of weight, tremor, distaste for meat—certainly suggest, as pointed out by Dr. Gale, that at great heights the gland may take on abnormal secretory activity. The matter is of importance and could easily be decided by animal experimentation. It seems not unlikely that the ration equipment of the expedition was not selected with any special regard to its content of iodine, on which the normal functional activity of the thyroid is dependent. It may be suggested that at the next attack on the mountain the climbers should be provided with cod-liver oil as part of their ration. This would provide an additional source of fats, as well as iodine sufficient to maintain the thyroid in a normal state of activity, and an abundance of certain vitamins without which the gland will not function normally.—I am, etc,

Eastbourne, Jan. 3rd.

R. MCCARRISON.

#### "E.R.A." TREATMENT.

SIR,—May I, on behalf of a small British society of doctors who employ Abrams's methods of treatment, take this opportunity of removing all possible misunderstanding by saying that charges of quackery and unethical conduct cannot be made against this society, which therefore is entirely distinct from what is ordinarily known as the "Abrams cult"? Widespread misconception appears to necessitate certain explanations in this connexion.

In the first place, whatever private views individual members of the society may have held, it is certainly a fact that Dr. Mather Thomson, its president, has never in the course of his teachings made extravagant claims either in relation to diagnostic or therapeutic achievement.

In the second place, it has always been the desire of the society to remove the inevitable reproach attached to the employment of Abrams's treatment as a "secret remedy." A long time ago we made unsuccessful application to the leaders of the cult in America for full information concerning the machines used, and subsequently my proposal that we should ourselves explore the mechanism of the instruments supplied and publish all details was unanimously agreed to at a meeting of our society.

Dr. Scott's book, therefore, which you have lately reviewed (January 3rd, p. 25), is, in respect of disclosure of knowledge, in full accord with the wishes of the other members of the society. Nevertheless it is perhaps advisable to add that all of us do not yet share his satisfaction that electrical pressure affords a true explanation of the results, or that machines constructed purely on this principle will necessarily produce results equal in value to those produced by Abrams's apparatus. Further investigations, likely to be prolonged and difficult, are to be made into the possibilities of radiation.

Now that the subject is receiving a greater measure of consideration than before, it seems only right and fair that the position of genuine Abrams workers in this country should be properly appreciated. Hence I hope you will excuse this trespass on your valuable space.—I am, etc.,

Beckenham, Jan. 3rd.

J. KENELM REID.

SIR,—In acknowledging the conspicuous fairness of your reviewer towards my small work, "*The Abrams Treatment*" in *Practice: An Investigation*, I feel that I should name the three medical men without whom the investigation could hardly have been possible—namely, Dr. MacLeod of Bristol and Drs. Hetherington and Mather Thomson of London. The bulk of the cases examined were from the practice of the last-named, who spared himself no trouble to afford the fullest facilities for the inquiry.

If, in the words of your reviewer, I have been fortunate enough to isolate a kernel of truth from the "E.R.A." doctrines (and medical men are now able to test the matter for themselves), I am also in a position to know with what *ingenuity* the truth was covered up. The responsibility for this rests with Abrams and his clique, and I think it right

to say that among the "E.R.A." practitioners whom I met in the course of the inquiry I found nothing but candour and a desire to discover the truth.—I am, etc.,

London, W., Jan. 5th.

G. LAUGHTON SCOTT.

#### HEADACHE.

SIR,—In the discussion on headache at a recent meeting of the Hunterian Society, my fellow specialists, Mr. Philip Franklin and Dr. Kelson, and I, in our anxiety not to overstate the case for the influence of nasal disease on the production of headache, went almost to the opposite extreme. We might well have emphasized the point frequently discussed in our special sections, of the pressure of enlargement, absolute or relative, of the middle turbinate body in many cases of headache, and of the relief afforded by the removal of the redundant portion. The enlargement may act in two ways, namely: actual pressure on the sensory nerves, increasing or diminishing with the oscillations of congestion and anaemia of the part, or obstruction to the outflow of secretions from the adjacent air spaces, maxillary, frontal, ethmoidal, or sphenoidal. The partial removal of this body is a fairly stereotyped proceeding, especially in an otherwise normally constructed nose, and the relief afforded is usually most striking. If the headache is temporarily diminished by the application of cocaine, or preferably of a combination in ointment form of anaesthetic and adrenaline, the probability of a good result is all the greater.

My friends Mr. Franklin and Dr. Kelson concur with me in these views.—I am, etc.,

London, W.I, Jan. 5th.

JAMES DUNDAS-GRANT.

#### PULMONARY TUBERCULOSIS TREATED BY SPÄHLINGER'S SERUM.

SIR,—With reference to the case of pulmonary tuberculosis treated by Spählinger's serum at Geneva, described in your issue of January 3rd (p. 43) by Drs. Steplani and Hudson, it would appear, if the clinical facts and the radiological findings have been truly interpreted, that this method of treatment promises to revolutionize not only our therapeutic but also our pathological outlook in tuberculosis of the lungs.

It is stated that a patient, who was practically in extremis, and who had "signs of extensive softening in both lungs," had, after ten weeks' treatment, secured complete arrest of the disease, that chest examination indicated "complete clearing up of the physical signs," and that the "improvement" was confirmed by radioscopy. The radiogram before treatment shows dense opacity at the right apex and at the middle third of the left lung. After treatment both lungs are shown as perfectly clear. Are we to conclude, therefore, that the Spählinger treatment not only clears away all tuberculous deposit, but also removes the fibrous tissue formation which, up to now, has been generally regarded as essential for the healing of a tuberculous lung?

It may be that the reproduction of the reduced radiogram does not give an accurate idea of the appearances on the negative; if so, it might save misconception if further information could be given on the point.—I am, etc.,

J. M. JOHNSTON,

Murkle, Aberdeenshire,  
Jan. 5th.

Medical Superintendent, Tor-na-Doo  
Sanatorium.

#### CANCER MORTALITY IN MENTAL INSTITUTIONS.

SIR,—In my letter published in the *JOURNAL* of February 23rd, 1924 (p. 352), I pointed out the fallacy which may arise from considering only the rate of cancer mortality per 100 deaths in the insane. Nevertheless, I think the statement in the Board of Control's report—namely, "and there is reason to believe that in this class [that is, the insane] there has been no such progressive increase of this disease [that is, cancer] as is believed to have occurred in the general population"—is correct.

It appears to me that Dr. Stocks (December 13th, p. 1136) has not considered sufficiently the average age of the

insane in institutions. In the Board's report for 1921 (p. 13) it is stated that per 1,000 living in the general population above 15 there are 502 males and 494 females between 15 and 34, whereas in the insane admissions of 1920 the numbers are 327 and 309. I have not the figures of the ages of the total number of the insane resident in institutions, but, taking one of the annual reports of the Cardiff City Mental Hospital, I find 101 males and 79 females were from 15 to 34 years of age, and 232 males and 251 females above 34. Thus in the general population above 15 roughly 50 per cent. are over 34 years of age, in the insane admissions 68 per cent., in the total resident in the mental hospital indicated 73 per cent. Obviously, then, the proportion of those of the cancer age in mental institutions is considerably higher than in the general population. Further, while the large number of the insane dying from tubercle and general paralysis is one of the main causes of the small percentage of cancer deaths, the death rate from tubercle has fallen from 15.7 per 1,000 resident in 1909 to 10.4 in 1923, and the paralytic admission rate has fallen from 7.6 per cent. in the period 1878-1914 to 5.7 per cent. in 1920-22. The cancer rate is much the same as in the years just preceding the war.

There are two further points in connexion with this subject on which statistics might be of value—(1) the cancer incidence in private mental institutions as compared with public (from the point of view of the more liberal dietary in the former); (2) the cancer incidence in Poor Law institutions, excluding cases admitted with cancer, the mode of life being somewhat similar to that in public mental institutions. —I am, etc.,

Hastings, Dec. 15th, 1924.

HARVEY BAIRD, M.D.

#### FREUDIAN DOCTRINE.

SIR,—In response to your invitation appended to Sir Bryan Donkin's letter (December 20th, 1924, p. 1177), may I state, on behalf of the British Psycho-Analytical Society, that we are prepared at any time, by appointing representatives, to participate in any suitable conference, symposium, or discussion on psycho-analysis arranged by any medical or other scientific society.

It is only fair to add, however, that in my opinion the need for such a conference is less urgent than Sir Bryan Donkin's misapprehensions lead him to suppose. It is true that we have been scrupulous in refraining from answering in public, particularly in the public press, the constant stream of abusive attacks evidently designed for the popular mind, but solely because we judge it more correct to confine such a discussion to a more fitting audience. But he is misinformed in saying that no discussion similar to the French one has taken place "under the auspices of any medical or scientific body in Great Britain." If he searches the records of the British Association, the British Medical Association, the International Congress of Psychology recently held at Oxford, or many other such meetings, he will find that there have been already a number of such discussions. Before the most appropriate body of all—I refer to the "Medical Section" of the British Psychological Society—the symposiums, papers, and discussions of the past few years have been mainly on the topic of psycho-analysis. Nor is he correct in saying that there was no discussion when I read my paper before the Royal Anthropological Institute.

Nor is it true, as he states, that of the two attacks on psycho-analysis recently published—by which he presumably means the books by Mr. Wohlgenuth and Dr. McBride—"neither has been replied to by any prominent advocate of this doctrine." Both are fully discussed in the *International Journal of Psycho-analysis*, which, as the organ of the "International Psycho-Analytical Association," is surely the most appropriate place to find an answer to them; the *British Journal of Medical Psychology* also published a critical notice of Mr. Wohlgenuth's book, more than eight pages long, written by Mr. J. C. Flügel, a member of this society.—I am, etc.,

ERNEST JONES,  
President of the British Psycho-  
Analytical Society.

London, W.1, Dec. 20th, 1924.

#### EARLY DIAGNOSIS OF APPENDICITIS.

SIR,—Sir Berkeley Moynihan for years past has consistently advised medical men to have nothing to do with the non-operative treatment of appendicitis, however apparently trivial the case.

This advice, given with incisive charm (and intent) and with all the weight derived from his commanding position in the profession, cannot fall flat. He considers, however, that it falls on stony ground, judging by the number of serious cases he gets.

Most experienced practitioners have had apparently slight cases that have suddenly shown their real character, and know that his advice is sound wisdom. It is exactly the same kind of wisdom that is involved in the business man's advice to have nothing to do with a thief.

The real difficulty is to know when you are dealing with a thief or with appendicitis. Just as men everywhere deal with the courteous stranger and occasionally, too late, find a thief, so medical men deal with large numbers of abdominal cases and occasionally find a definite appendicitis hitherto only vaguely suspected. All that either can do is to use precaution: not to lend money to the one nor to conclude there is no appendicitis because there is no rise of temperature, no increase in pulse rate, no sufficiently localized pain, no tenderness that does not come under suspicion owing to the educated person's knowledge of where the appendix is, no resistance to pressure, no tangible swelling. There may, twenty-four hours later, now and again he found a gangrenous appendix.

The wise man waits for an established character before he lends; and the medical man can only wait, examine, and re-examine, and adopt Sir Berkeley's advice if and when appendicitis becomes evident; but I am personally satisfied operative surgeons cannot expect all their cases to be early ones. The ground may have yielded no fruit, not because it was stony, but because there was not sufficient light.

Here lies real ground for research, especially by men in general practice. May it be well lit!—I am, etc.,

Leeds, Jan. 1st.

RALPH HORTON.

#### REX v. BATEMAN.

SIR,—Permit me, as the wife of Dr. Percy Bateman (423, New Cross Road), through your columns to thank those loyal gentlemen who so ably defended my husband in court, also in your valuable journal. My husband got out of his bed to do all in his power to help this poor woman, and his reward is to be branded in a court of justice as a criminal.—I am, etc.,

London, S.E.14, Jan. 4th.

M. BATEMAN.

#### Obituary.

WILLIAM ARNOT PARKER, M.B., C.M.,  
Medical Superintendent, Glasgow District Asylum,  
Gartloch, Gartcosh.

Yet another well known name falls to be added to the already lengthy list of losses sustained by the medical profession of Glasgow and the West of Scotland during the year that has just passed. A few of these names may have been more widely known, but none could be held in higher esteem than was that of Dr. Parker of Gartloch by those whose privilege it was to have been associated in any way with him.

William Arnot Parker was born near Glasgow in 1865. He was educated at the High School and the University of Glasgow, graduating M.B., C.M. in 1889. After two voyages as ship surgeon he joined the staff of the City of Glasgow Fever Hospital, Belvidere, under Dr. James W. Allan. Early in his career he began to evince special interest in mental diseases, and was assistant medical officer and pathologist to the County Asylum, Lancaster. After a few years he was appointed assistant medical officer at the Glasgow Royal Asylum, Gartnavel. From 1897 till 1901 he was senior assistant at the Glasgow

District Asylum, Gartloch, becoming medical superintendent there when Dr. Oswald was appointed medical superintendent of Gartnavel. This position Dr. Parker held with great honour and distinction till his death. Under his direction at Gartloch many notable extensions and improvements were made, including the increase of bedding accommodation from 540 to 810, and the introduction of a modern sanatorium to accommodate 60 patients.

Dr. Parker was one of the first to advocate the open-air treatment of acute mental cases in bed, and the spacious verandahs he introduced at Gartloch early in 1903 were the first of the kind to be used in Scotland, and were amongst the forerunners of the modern verandahs to be found in practically all asylums in this country to-day. He was especially interested in research work, and the extensions of the pathological laboratory and the establishment of well equipped electrical and haematological rooms were evidences of his energy in this direction. When the Scottish Western Asylums Research Institute was founded in 1909, he was appointed the first honorary secretary and treasurer, offices he held for several years. It was his intention that further large extensions at Gartloch should be carried out, and plans had actually been prepared, but progress in this direction was interrupted by the war.

He endeared himself to his patients and staff alike and, in fact, to all with whom he came in contact, by his gentleness of manner and his kindly sympathy and encouragement at all times.

He married, in 1909, a sister of Dr. Charles James Lewis, associate professor of public health in the University of Birmingham, and his home life was particularly happy. For the past two years he had been in failing health, and he died on December 24th, 1924. His remains were followed to the grave in the Glasgow Necropolis by a large gathering of relatives and friends, representative of the public life of Glasgow, the medical profession, and his staff, past and present. He is survived by his widow and four young children, to whom, along with his sister and two brothers (one of whom is Professor Matthew Parker of the University of Winnipeg, Canada), the deepest sympathy is expressed in their great loss.

Dr. FREDERICK BURROUGHS JETTERISS, who died on December 20th, 1924, received his medical education at King's College, London. He obtained the diplomas M.R.C.S.Eng., L.R.C.P.Lond. in 1900, and the F.R.C.S. Edin. in 1905. He was for many years medical officer and public vaccinator of the East Chatham division of the Medway Union, and his other appointments included house-physician to King's College Hospital and surgeon to St. Bartholomew's Hospital, Rochester. He took an active interest in ambulance training, and was honorary surgeon and examiner to the St. John Ambulance Association and lecturer on ambulance to the South-Eastern and Chatham Railway; he was lately made an Associate of the Order of St. John of Jerusalem. He served for twelve years in the R.A.M.C.(T.), being attached to the 5th battalion of the Royal West Kent Regiment, with which he served in India from the beginning of the war, and later on in Mesopotamia, reaching the rank of lieutenant-colonel.

Dr. JOHN REGINALD LAMBERT, who died on December 26th, 1924, at the age of 50, was educated at Bradford Grammar School and Leeds University. In 1897 he graduated M.B., Ch.B.Vict., and received the diplomas L.R.C.P. and S.Ed. and L.R.F.P.S.Glasg. He then joined his father, Dr. F. Lambert of Farsley, on whose death he took sole charge of the practice. He was appointed medical officer of health for Farsley, and was medical officer for Farsley district and public vaccinator of Calverley with Farsley N. Bierley Union. He took an active interest in sport, was president of the Farsley Cycling Club, vice-president of the Farsley Cricket Club, and vice-president of the Farsley Celtic Association Football Club since its start. Dr. Lambert is survived by his widow and eight children. He was a member of the British Medical Association. His general popularity was very great, and his funeral was attended by 900 people.

Dr. LÉON CREINISSE, a well known writer on the staff of the *Presse Médicale*, and formerly attached to the now defunct *Semaine Médicale*, was recently killed by a taxicab in Paris.

## Universities and Colleges.

### UNIVERSITY OF LONDON.

At the meeting of the Senate on December 17th, 1924, it was decided that the Department of Bacteriology and Public Health at King's College should be closed at the end of the session 1924-25.

It was resolved to amend Regulation 4, Part B (ii), for the Diploma in Psychological Medicine, to read as follows:

(iii) Psychological Medicine. (Two papers and a clinical and an oral examination.) In order that candidates may have the option of showing either (a) a higher knowledge of mental diseases and a less advanced knowledge of mental deficiency, or (b) a higher knowledge of mental deficiency and a less advanced knowledge of mental diseases, paper I will be a general paper to test the candidate's knowledge of both mental diseases and mental deficiency, and part II will be special, and will consist of two separate alternative sections, the first relating to mental diseases, and the second section to mental deficiency. Candidates will be permitted to take only one of the two sections of paper II at one and the same examination, and each candidate must state at the time of entry which of the two sections he will take.

Other amendments and additions to the regulations for the Diploma in Psychological Medicine were also adopted.

Sir H. J. Waring, M.S., F.R.C.S., was nominated for appointment to represent the University on the Westminster Hospital Medical School Committee.

Dr. Herbert G. G. Cook has been reappointed the Vice-Chancellor's representative on the Court of Governors of the University College of South Wales and Monmouthshire.

A lecture on the relation of paralysis agitans to the Parkinsonian syndrome of epidemic encephalitis will be given at the house of the Royal Society of Medicine, 1, Wimpole Street, W.1, by Dr. H. Cruchet, professor of pathology and general therapeutics in the University of Bordeaux, on Wednesday, February 25th, at 5 p.m.; Sir Humphry will take the chair.

Professor B. will give a course of four lectures on puerperal sepsis, at St. Thomas's Hospital Medical School, on March 2nd, 3rd, 4th, and 5th at 5 p.m.

A course of four lectures on some practical considerations and experiences in the conservative treatment of fractures of the pelvis and the lower extremity will begin at St. Bartholomew's Hospital Medical School by Sir William Wheeler, past president of the Royal College of Surgeons in Ireland, on February 16th, 17th, 18th, and 19th, at 5 p.m. The chair will be taken at the first lecture by Mr. Walter G. Spencer, M.S., F.R.C.S. Admission to these lectures will be free without ticket.

## The Services.

### PASSAGES TO INDIA.

MAJOR M. PURVIS (Helenburgh, Dumfriesshire) writes: After reading your remarks, in a recent number of the JOURNAL, as to the benefits resulting to the Indian Medical Service from the acceptance by H.M. Government of certain recommendations of the Lee Commission, I applied to the India Office for passage at the public expense on my return to India from leave in March. In reply I have been informed that "the provisions of the Superior Civil Services (Revision of Pay and Pension) Rules, 1924, apply, so far as officers of the Indian Medical Service are concerned, only to those who are in permanent civil employ." It would appear, therefore, that those who, like myself, are serving on the military side of the Indian Medical Service do not reap any advantages from the recommendations of the Commission. My object in writing is to make this point clear, so that other officers of the I.M.S. on the military side may not suffer from a misapprehension.

### DEATHS IN THE SERVICES.

Surgeon Commander William Ernest Marshall, R.N.(ret.), died very suddenly at Treniole, Launceston, on December 24th, 1921, of heart failure, aged 58. He was born at Portsmouth in 1865, educated at University College, London, and after taking the surgeon of the Royal Portsmouth Hospital. He entered the navy abroad in November, 1891, and after ten years' sea service Haulbowline, and promoted to staff surgeon in the following year. From 1904 to 1906 he served in H.M.S. *Bulford*, and after she was Hospital. He was promoted to fleet surgeon on November 11th, 1907, and served successively in H.M.S. *Andromeda*, *Achilles*, and *Edinburgh*; he was in her at Malta in August, 1914, when the war began, and took part in the pursuits of the *Geben* and *Breslau*. After a short spell on convoy duty in the Indian Ocean and Red Sea, during which a Turkish fort was bombarded and destroyed opposite Perim, the *Duke of Edinburgh* was sent to Scapa Flow subject of this notice was invalided for heart disease, and since then had lived near Launceston. He was twice married, and leaves a widow, and also two children by his first wife.

## Medical News.

LETHARGIC ENCEPHALITIS was unusually prevalent in 1924 in Great Britain and Ireland, though, apart from Italy and Sweden, where smaller outbreaks have occurred, it was not observed so frequently on the European continent as during previous years. It reached a maximum in the middle of May, in England, and early in June in Scotland; in 1923 the greatest number of cases were notified in March, and in 1921 in February. The decline of the epidemic was slow, and the number of notifications became stabilized in September and October at a very much higher level than in previous years. The type of disease differed from that of earlier outbreaks in that the case fatality rarely exceeded 20 per cent., whereas formerly it had been 50 per cent. The onset often resembled influenza, and abortive attacks were frequent. The usual oculio-lethargic type was less common than during earlier epidemics, and many cases were characterized by myoclonic symptoms.

THE Imperial Bureau of Entomology has issued an index (price 9s. net) to Volumes I to X (1913 to 1922) of the *Review of Applied Entomology*, Series B: Medical and Veterinary. This index will greatly increase the value of the *Review* as a work of reference, and will also tend to simplify difficulties in nomenclature, which have resulted from many insects having been recorded under different names in different volumes. Arthropod names only are included, and for such entries as diseases and blood parasites, their vertebrate hosts, and their geographical distribution, reference must still be made to the annual index published with each volume. The general arrangement of this combined index is the same as that of the annual indexes, except that in the case of authors reference is restricted to those whose papers have been actually abstracted in the *Review*.

POST-GRADUATE courses on diseases of the nervous system will begin next month at the National Hospital for the Paralysed and Epileptic. There will be a general course beginning on February 2nd, consisting of clinical lectures and demonstrations, teaching in the out-patient department, and pathological lectures and demonstrations. The fee for this course will be five guineas. If sufficient applications are received a course of lectures on the anatomy and physiology of the nervous system will be arranged (fee, two guineas). A course of clinical demonstrations, chiefly on methods of examination of the nervous system, will also be given (fee, two guineas). A course of ten lectures and six demonstrations on neurological ophthalmology has also been arranged (fee, five guineas, or if taken with the general course, three guineas). The number of students in this class will be limited, and early application should be made to the Secretary of the Medical School (Queen Square, London, W.C.1.). A limited number of students can be enrolled as ward clerks or clinical assistants in the out-patient department.

THE Fellowship of Medicine announces that the London Temperance Hospital, in conjunction with Bethlem Royal Hospital, the Central London Throat, Nose, and Ear, the Royal Eye, St. Peter's, and the West End Hospital for Nervous Diseases, will hold a post-graduate course in general medicine, surgery, and the special departments from January 12th to 24th. A four weeks' course in urology will be held at St. Peter's Hospital from January 12th to February 7th. The following courses will be held in February: A fortnight's intensive course at the Prince of Wales's General Hospital, Tottenham; a combined course in children's diseases at the Paddington Green Hospital, Victoria Hospital for Children, and the Children's Clinic; a dermatological course at the St. John's Hospital; a gynaecological course at the Chelsea Hospital for Women; a course in tropical medicine at the London School of Hygiene and Tropical Medicine; and in venereal disease at the London Lock Hospital (Dean Street). Copies of the syllabus of each course may be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W.1.

SERIOUS losses in apples shipped from Australia and Tasmania in 1922 were incurred owing to many of them becoming affected with "brown heart," a functional disease which it has been ascertained is due to want of ventilation, or, as the Agent-General for Tasmania, the Hon. A. H. Ashbolt, put it, to "suffocation" (see BRITISH MEDICAL JOURNAL, August 25th, 1923, p. 335). The assistance of the Food Investigation Board of the Department of Scientific and Industrial Research was enlisted, and that Board has now issued through the Stationery Office (price 9d. net) a report (No. 20) giving a general survey and summary of the results obtained by a scientific expedition to Australia in 1923. The evidence obtained by the expedition, together with that

already published, indicates that "brown heart" is developed on shipboard, that the conditions which give rise to it are those accompanying insufficient ventilation of the hold, and that they can be guarded against and all danger of the occurrence of the disease eliminated.

THE KING has appointed Sir William Fairbank, K.C.V.O., O.B.E., to be Honorary Surgeon-Apothecary to the household at Windsor Castle.

At a meeting of the Medico-Legal Society at 11, Chandos Street, Cavendish Square, W., on Tuesday, January 20th, at 8.30 p.m., Mr. F. Llewellyn Jones, coroner for Flintshire, will read a paper on the laws of nations and the health of nations.

ON the report of the examiners (Sir William Willcox, Dr. Alfred Pincey, and Dr. Knyvett Gordon) the directors of Virol, Ltd., have awarded the company's research scholarship to Mr. R. A. Hickling, B.A. Cantab., M.R.C.S., L.R.C.P., demonstrator of pathology at Charing Cross Hospital. The scholarship is of the value of £200 for one year.

A MEETING of the Guild of Public Pharmacists will be held at St. Bartholomew's Hospital on Thursday, January 15th, when a lecture will be given on the influence of suggestion in social life, by Sir Robert Armstrong-Jones, C.B.E., M.D. Lord Stanmore (Treasurer of the Hospital) will take the chair at 8 p.m. The pharmaceutical departments will be open to visitors from 7 o'clock.

THE New York State Department of Labour last summer began the publication of a monthly *Industrial Hygiene Bulletin*, giving in popular language information with regard to industrial diseases and risks. The issue for December last contains a note on the danger of poisoning by tetraethyl lead, a substance which, it has been suggested, might be used to improve the efficiency of gasoline motors. It can only be used with safety in motors when extremely diluted, usually 1 to 1,000.

THE permanent committee of the International Congress for Industrial Accidents and Professional Diseases, which has not held a session since 1912, was reconstituted at a meeting in Amsterdam on December 21st, 1924. Sir Thomas Oliver (England) and Dr. Kaufmann (Switzerland) were elected honorary presidents. The next congress will be held in Amsterdam on September 7th, 1925. An English committee is being formed under the presidency of Sir Thomas Oliver. Further particulars can be obtained from the honorary secretary of this committee, Dr. H. S. N. Menko, 2, Grosvenor Gardens, Cricklewood, N.W.2.

THE late Dr. T. Sydney Short of Birmingham left estate of the gross value of £45,861, with net personality £42,691.

THE eighteenth French Medical Congress will be held at Nancy from July 16th to 19th, 1925. Professor Simon of Nancy is the president, and Professor Dr. G. Etienne of Nancy the general secretary. The three principal subjects for discussion are: aortic pectoris, introduced by Dr. Gallavardin and Professor Richou; acidosis, introduced by Professor Labbe, Dr. Nepveux, Professor Petren of Sweden, and Dr. Dantrebant of Brussels; and pulmonary gangrene, introduced by Professors Bezançon, de Jong, Parisot, and Caassade. In connexion with this congress arrangements are being made to visit Metz, the Graud-Courroue, and other places of interest in the neighbourhood. Inquiries should be addressed to the secretary, 32, Faubourg Saint-Jean, Nancy.

A CONFERENCE on congenital syphilis organized by the French National League for Combating the Venereal Peril will be held in Paris, under the presidency of Professor Jeanselme, at the beginning of October, 1925, immediately after the congress of French-speaking gynaecologists and obstetricians.

APART from numerous local journals in all the university centres, there are thirty-five medical journals in existence in Russia, almost all of which are published at Leningrad or Moscow.

THE Department of Biology, Georgetown University, Washington, D.C., announces that the commission for the distribution of the prize for cancer study founded by Dr. Sofia A. Nordhoff-Juag will in future be awarded every two years, and its amount will be 1,000 dollars. The next award will be made in 1926.

THE Scientific Press, Ltd., announces that the 1925 edition of *Burdett's Hospitals and Charities*, the Year Book of Philanthropy and the Hospital Annual, will be published this month. It provides an exhaustive record of charitable work during the past year, and is a reliable guide to British and Colonial hospitals and kindred institutions.

DR. MERCIER of Tours has been nominated professor of clinical medicine in the medical school there.

DR. MANUEL SÉRÉS, professor of descriptive anatomy, has been appointed dean of the medical faculty of Barcelona.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *BRITISH MEDICAL JOURNAL* alone unless the contrary be stated. Authors desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication.

ALL communications with reference to advertisements as well as orders for copies of the *JOURNAL* should be addressed to the Financial Secretary and Business Manager, 429, Strand, London, W.C.2. Attention to this request will avoid delay. Communications with reference to editorial business should be addressed to the Editor, *BRITISH MEDICAL JOURNAL*, 429, Strand, W.C.2.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

The telephone number of the *BRITISH MEDICAL ASSOCIATION* and *BRITISH MEDICAL JOURNAL* is Gerrard 2630 (Internal Exchange). This telegraphic addresses are:

EDITOR of the *BRITISH MEDICAL JOURNAL*, *Litology Westrand*, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand*, London.

MEDICAL SECRETARY, *Mediscera Westrand*, London.

The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone: 4361 Central).

### QUERIES AND ANSWERS.

"B." asks for advice in the prevention of chilblains and in the treatment of those threatening to suppurate. The usual remedies, including calomel and parathyroid, have been tried.

"B. A." asks for advice in the treatment of a man aged 40 with dermatitis exfoliativa. He has been in hospital for six months and is not cured.

#### MOSQUITO BITE.

DR. E. B. FENNELL (Hayle, Cornwall) asks for a remedy to apply at once to a mosquito bite. A member of his family was bitten and the bite was followed instantly by swelling and intense itching, and, within twenty-four hours, by alarming attacks of faintness, vomiting, and profuse perspiration.

#### WHOLEMEAL BREAD.

DR. C. E. SHELLY of Hertford has been good enough to reply as follows to an inquiry was recently transmitted to him: "Wholemeal flour and bread can be obtained from any reputable baker. It contains all the components of the wheaten grain—bran, germ, endosperm—chiefly starch—and (unless the flour has been bleached) the vitamins. But it is not well tolerated by most people: the irritating bran is apt to cause flatulences and an irregular diarrhoea; it soon palls upon the taste; it makes but poor and unattractive pastry, and it does not keep well. Wholemeal flour from which the bran only has been removed is free from these objections. It is usefully distinguished as "stone-milled flour," and the bread and pastry made from it are attractive, nutritious, and digestible. Such flour and bread can be obtained from Messrs. J. and B. Stevenson, Ltd., Battersea Bakeries, Battersea, S.W.11. Other addresses in London and its neighbourhood have been given in the *Times* from time to time during the last few months. Local bakers can generally be induced to obtain this flour and to make bread from it.

### LETTERS, NOTES, ETC.

#### SEA-SICKNESS.

In connexion with Mr. Vincent Moxey and Mr. Bertwistle's notes in our issues of December 6th, 1924 (p. 1040), and December 13th (p. 1144) respectively, on the treatment of sea-sickness, Dr. P. F. Sturridge (Sutton Benger) recalls that there have been previous account in our issue of January 3rd, 1920 (p. 23), of the investigation recommended the use of atropine in combination with adrenaline. Dr. G. W. Maw also reported in favour of atropine that it was useless when sickness had once started. Dr. Sturridge relates that he tried atropine early in 1920 during a voyage from Avonmouth to Jamaica which began with a storm. He and his wife received hypodermic injections of gr. 1/60 before leaving port, and repeated the dose in the evening. Although

the sea was very rough and the steamer small, neither of them missed a meal during the whole voyage of fourteen days. Two delicate young girls were very ill with sea-sickness and could not leave their cabins; on Dr. Sturridge's advice the ship surgeon prescribed atropine tablets; as a result both patients were immediately cured of sea-sickness and came on deck. Two years ago Dr. Sturridge gave atropine tablets to his brother, who was about to start on a similar voyage with a delicate wife and daughter; none of them were sea-sick throughout. He has advised other travellers to ask to be treated in this way, and has heard of good results.

\* \* A combination of atropine and strychnine has been recommended by other investigators, and hyoscyne has also given good results. Both these remedies can be administered in the form of small pills. A dose suggested is atropine gr. 1/100, strychnine gr. 1/60. One of these pills is swallowed one to two hours before the boat leaves port, and another is allowed to dissolve slowly in the mouth if any gastric uneasiness is experienced or the motion of the ship becomes unpleasant. In this way complete freedom from nausea and sickness has been obtained, although headache may occur. For short journeys, such as the Channel crossing, this method has the additional advantage in that it does not interfere with the appetite, and also that the benefit persists for some hours during such a train journey as that across France. These pills have been used with success in cases of train sickness also.

#### REMEDIAL EXERCISES FOR RECTAL AND UTERINE PROLAPSE.

DR. C. WESTMAN (London) writes: In the *JOURNAL* of December 6th, 1924 (p. 1041) Dr. T. Stacey Wilson drew attention to the benefit of exercises for the pelvic floor muscles in cases of prolapse of rectum and uterus. Dr. A. Hurst, who is never likely to pass by any therapeutic means of value, has already had fifteen years' experience of them. This fact speaks for itself, and it is to be regretted that the method is not more generally known. Dr. Hurst further observes that "it is a curious fact that those who are specially interested in remedial exercises entirely ignore the extremely important muscles which form the pelvic floor." I am sure Dr. Hurst will be glad to know that this statement is not entirely according to fact, because pelvic floor exercises have been known and practised, at least by Swedish experts in remedial exercises, for many, many years. Our difficulty, however, has been lack of sufficient opportunity of showing the great benefit from such measures. In certain cases of prolapse speedier results are obtained from a combination of remedial exercises with rectal faradization. I think the electro-stimulation has a particular value in severe cases where loss of sensation to muscular contraction is marked. The rhythmic contractions set up by the faradic current prepare, as it were, the patient for his own muscular efforts. These should, of course, never be left out, and certain remedial exercises can with great advantage be practised at home.

#### HERPES AND VARICELLA.

DR. JOHN PORTELLI (Province Wellesley, Straits Settlements) writes: On October 29th last I received a telephonic message from a rubber plantation asking me to visit a case of suspected small-pox in an Indian coolie. The case turned out to be one of chicken-pox, the diagnosis being based on the following points: great inequality in stage of development of the rash in various parts (the rash affected the forehead, the face, and the anterior aspect of the thorax); the lack of constitutional disturbance and of any history of it (the rash had appeared two days previously); the patient had been successfully vaccinated seven months previously. I was unable to trace the origin of the infection. The patient occupied a room with two other coolies. As a precaution against further spread of the infection amongst the labour force of the estate these two men were segregated. On inspecting them I found that one of them had recently had a patch of herpes in relation to the sixth left intercostal space, and extending from the mammary to the anterior axillary line. He stated that the "tiny blisters" had appeared about three weeks before and dried up about ten days afterwards. He had no eruption anywhere else and no general disturbance beyond the pain of the herpes. The treatment consisted of local soothing remedies. Four other cases of chicken-pox have since occurred on the estate. Careful investigation has failed to reveal the source of origin of this limited outbreak. There seems to be a close relation between the first case of chicken-pox and the case of herpes.

THE Hillman Motor Car Company, Ltd. (Coventry), announces that the prices of Hillman cars for 1925 have been reduced as from January 1st as follows: 11-h.p. chassis, £240; 11-h.p. 2-3 seater, £320; 11-h.p. 4-5 seater, £335.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments in hospitals, will be found at pages 38, 39, 41, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 27.

## An Address

ON

THE INFLUENCE OF CHEMICAL RESEARCH ON  
MEDICINE AND FORENSIC MEDICINE.DELIVERED TO THE JOINT MEETING OF THE MANCHESTER SCIENTIFIC  
SOCIETIES, NOVEMBER 7TH, 1924,

BY

SIR WILLIAM WILLCOX, K.C.I.E., C.B., C.M.G., M.D.,  
F.R.C.P., F.I.C., B.Sc.

CHEMISTRY at the present day may rightly be described as an exact science. It is only during the last hundred and fifty years that it has become so, and it is well to remember what a debt chemistry owes to physics for its present prominent position amongst the exact sciences.

The discovery and perfection of instruments adapted for accurate quantitative measurements, the discovery of those important physical laws with which are associated the honoured names of Boyle, Marriotte, Gay-Lussac, Dalton, Charles, Berzelius, and Avogadro, formed the basis of the development of chemistry as an exact science. With such a sure foundation the progress of chemistry became stable and assured, and in later years it may be said to have advanced by leaps and bounds.

Medicine has been closely linked with chemistry from the earliest times, and each in the earlier times of its development has owed much to the other. During recent years medicine has gained enormously from chemical research, and chemistry may be truly said to be the main foundation of modern medicine.

Medicine at the present time may be described as an "applied science." Many of its problems have been too difficult for solution beyond possibility of dispute, and theories and speculation still occupy a prominent position in the medicine of to-day. Thanks to the researches in chemistry and the ancillary sciences, many of the problems in medicine are being elucidated, so that as time advances theories and speculations are being gradually displaced by deductions based on exact scientific observations.

It is doubtful, however, if medicine can ever possibly become a science characterized by such exactitude as obtains in chemistry; too many complicated factors play a part in the processes of physiology and disease to render this attainable. Yet it is quite certain that the application of exact chemical methods in the solution of problems pertaining to medicine and physiology has done more than anything else to clear away error and to lead to the proper understanding of the difficulties with which they are confronted.

## HISTORY OF CHEMISTRY.

The development of chemistry may be divided into the following periods:

*The Alchemical Period (1500 B.C. to 1650 A.D.).*

It was during this period that scientific workers attempted the transmutation of metals, and the conversion of the baser metals, into gold. Some were working in a true scientific spirit, but it is to be feared that in many the hope of gain dominated their efforts. It must not be forgotten that it was in this period that the ancient Indian and Greek natural philosophers conceived the idea of atoms, and their conception was later on elaborated and formed the basis of the atomic theory enunciated by Dalton, which has played such a great part in the development of modern chemistry. During this period chemistry appears to have had little relationship with therapeutic medicine, but its association with toxicology was very close.

*Early History of Toxicology.*

Poisoning and antidotes for poisoning appear to have exerted a great fascination on the human race from the earliest times. The earliest writings contain accounts of poisons and their effects and possible antidotes. Xenophon (410 B.C.) relates that the use of poisons was so frequent amongst the Medes that it was an ancient custom for the cup-bearers to taste the wine before presenting it to the King. Criminal poisoning is referred to in Roman history in 331 B.C., when twenty matrons were surprised in the act of preparing a poison, which they were compelled by the magistrates to drink and from which they perished. Roman

law (82 B.C.) contains a legislative enactment dealing with the crime of poisoning, and a later enactment dealt with the use of poisons to procure abortion.

In the first century B.C., Mithridates, King of Pontus, was so interested in poisons that he personally conducted toxicological experiments on condemned criminals and others. He wrote a book on the subject and invented a universal antidote for poisons which Celsus describes as containing thirty-six ingredients. It is recorded that when Mithridates wished to commit suicide his constitution had been so long inured to antidotes that poison had no effect on him; he was therefore compelled to ask a mercenary to dispatch him with his sword.

With the Renaissance in Italy poisoning became a fine art. Political murder by poison was in those days considered to be quite legitimate in Italy, as is evidenced by the secret archives of the Council of Ten at Venice (1400 to 1500 A.D.). It was in this period that Pope Alexander VI and his son Caesar Borgia committed numerous murders by poison, and Pope Alexander VI himself fell a victim to poison in 1503, his butler giving him the poisoned wine intended for one of his victims.

Poisoning in England was not unknown at this period, and in 1531 a statute of Henry VIII ordered poisoners to be boiled to death. Down to the nineteenth century criminal poisoning was very common, and probably preparations of arsenic and corrosive sublimate were most commonly used. The methods of diagnosis of poisoning depended mainly on the supposed circumstances attending the administration. The *post-mortem* appearances in cases of poisoning appear to have been little understood, and importance was attached to signs such as lividity, discoloration of viscera, etc., which we now know to be merely ordinary natural *post-mortem* changes, and not in any way characteristic of death by poison.

Toxicology did not really make any great advance until the development of modern chemistry and the application of accurate analytical methods. It has been truly said that the only certain sign of poisoning is the identification and estimation by analysis of the poison in the body.

*The Iatro-Chemical Period (1500 to 1700 A.D.).*

In this period chemical investigations were closely associated with medicine, for the advance of which they were directed. Efforts were vainly made for the cure of all ills—the "elixir vitae." During this period phosphorus was discovered and improvements in many technical processes, such as the making and staining of glass and earthenware, were worked out. This period is of value to medicine in the discovery of sodium sulphate by Glauber, who extolled the virtues of his salt:

*The Phlogiston Period (1650 to 1775 A.D.).*

This period marked the efforts of scientific workers in endeavouring to explain the changes occurring in combustion and chemical combination. Their work, though much of it was unfruitful, paved the way for, and was the precursor of, the next period—"the quantitative period"—in which the foundation of modern chemistry was well and truly laid.

*The Quantitative Period (1775 A.D. to the present time).*

This period marks the development and growth of modern chemistry. Oxygen was discovered by Priestley in 1774, and independently by Scheele in 1777. Hydrogen was discovered by Cavendish in 1766, and in his experiments on air he found that 1/120 part resisted change, thus foreshadowing the discovery of argon by Lord Rayleigh and Sir William Ramsay in 1894. Scheele discovered chlorine in 1774, but thought it was a compound. Gay-Lussac in 1809, and Davy in 1810, demonstrated the elementary nature of chlorine. Scheele discovered arseniuretted hydrogen in 1775 and hydrocyanic acid in 1783.

It is unnecessary to pursue further the numerous discoveries made in the early part of this period by men whose names are household words in the history of chemistry. It is interesting to note that these early workers made use of physiological experiments on animals in their researches. The discovery of the important elements and their compounds, the conception of the periodic law by Mendeleef in 1869, all led the way to further research and pointed the way to further discoveries. Urea was found in the urine in 1773 and was synthesized from ammonium cyanate by Wohler in 1828.

The foundations of toxicological analysis were laid by early work of this period. Thus the Marsh test for arsenic was discovered in 1836, and further perfected by Berzelius. In 1839 Orfila showed that in fatal cases of arsenical poisoning arsenic could be detected in the liver, spleen, heart, and muscles, and showed that analysis should be made not only of the alimentary tract but of other organs of the body. The importance of the absorption of poisons and the realization that it is the absorbed poison which causes death in most instances were thereby appreciated. In 1844 Fresenius and von Babo devised a method for the systematic research of all mineral poisons and for the destruction of the organic matter of the viscera as a preliminary to the analysis. This method of analysis is in common use to-day. In 1850 Stas discovered a process by which alkaloidal poisons could be extracted from

viscera, and this process in a modified form is the one in common use to-day in the toxicological analysis of viscera in cases of poisoning by alkaloids.

#### DEVELOPMENT OF CHEMISTRY.

Liebig (1803-1873) may be regarded as the founder of organic chemistry. He elaborated the methods of ultimate organic analysis by combustion, and he applied his knowledge to the development of physiology and agricultural chemistry. Liebig's work was the foundation of the chemistry of the proteins and metabolism.

Pasteur was a chemist who had perhaps the greatest outlook on science of anyone in history. He is indeed claimed as the founder of modern medicine, though he had no official medical qualification. In his early work much attention was devoted to crystallography, and his brilliant researches into the constitution of tartaric acid led to the discovery that the racemic variety consisted of a mixture of the dextro- and laevo-rotatory acids. This work led to the discovery of stereo-isomerism, and its application by later workers to innumerable other substances now known to exist in stereo-isomeric forms. Professor Frankland describes Pasteur as the founder of stereo-chemistry, one of the most wonderful developments of modern chemistry.

Pasteur, when appointed to a professorship in Paris, was asked to give his attention to the processes of fermentation, so important in the national industries. By his study of fermentation he was led on from discoveries in this sphere to the study and foundation of modern bacteriology. He demonstrated conclusively the germ theory, and showed in a famous lecture at the Sorbonne in 1864 that the theory of "abiogenesis" or spontaneous generation, advanced by Dr. Bastian in this country, was untenable. He demonstrated that the growth of organisms in sterile culture media only occurred after these had been inoculated with living organisms. The truth of *Omne vivum ex vivo* was demonstrated conclusively by his experiments, and this work was fully confirmed by Tyndall in England.

This work of Pasteur led to the study of wound infection by Lord Lister, and the birth of antiseptic and later aseptic surgery resulted. The human race owes an ineffable debt of gratitude to Pasteur and Lister for their researches, whereby wounds and surgical operations were delivered of the dread of infection by the organisms causing pyaemia, septicaemia, erysipelas, hospital gangrene, tetanus, etc. Countless lives have been saved by their careful work and its application by those who have followed them.

Pasteur's work is a splendid example of the great discoveries which may follow when the trained scientific worker applies himself heart and soul to the elucidation of problems in applied chemistry. Pasteur might not have been led on to the discovery of the germ theory and bacteriology had he not in the first place set himself to solve the various problems in applied chemistry which were so essential for the progress of the national industries of his country. His work on fermentation was followed by masterly studies in silkworm disease, anthrax, the *Vibrio septique*, and chicken cholera.

Pasteur went on from the determination of the cause of disease to discover methods of immunity, and in 1881 gave a successful public demonstration in France of the practical value of his immunizing methods in that deadly disease anthrax. Twenty-five sheep were previously protected by the injection of attenuated anthrax cultures. On a certain day these twenty-five protected sheep and twenty-five unprotected sheep were all injected with living anthrax bacilli. The immunized animals were unaffected, but the unprotected sheep all developed anthrax and died within a few days.

Pasteur's knowledge of immunity was so great that he discovered the means of immunizing persons already infected with rabies by the injection of emulsions of the attenuated spinal cord of infected animals. This method is still in use in all parts of the world at the present day, and the discovery is all the more remarkable when it is remembered that the organism causing rabies has not even yet been isolated.

Emil Fischer was a chemist to whom modern medicine and physiology owe an enormous debt of gratitude. His work on the proteins led to an understanding of the constitution of the protein molecule and the methods by which the metabolic processes in the body bring about its synthesis. His discovery of phenylhydrazine, which has been termed the "pathfinder of carbohydrate chemistry," led him on to the discovery of the constitution of the sugars, and formed the foundation of a more precise knowledge of carbohydrate metabolism and diabetes. He discovered veronal and a host of new drugs, whereby pharmacology was greatly advanced.

Paul Ehrlich, by his chemical studies and their application to medicine, has been one of the greatest benefactors of modern times. His experiments on dyes and tissue staining led to the discovery of the triacid stain, whereby histology was greatly advanced. He discovered the fuchsin stain for tubercle bacilli in 1882, and the sulpho-diazobenzol test for bilirubin in 1885. Perhaps Ehrlich's greatest work was his conception of the theory of immunity. This theory has been, and still is, the guide-post to numerous discoveries by other workers. Wassermann, the discoverer of the complement fixation test for syphilis and other diseases, stated that without Ehrlich's theory he could never have hit upon his special and reliable diagnostic test. This test is being applied with success in the diagnosis of other diseases such as tuberculosis, gonorrhoea, etc. Ehrlich's name will always be associated with the discovery of salvarsan and allied arsenbenzol derivatives which have been of incalculable value in the treatment of syphilis, relapsing fever, yaws, etc. Ehrlich, by his study of the blood corpuscles consequent on his perfection of staining methods, became the founder of haematology.

Modern medicine has become an applied science, and its advances are mainly due to the application of accurate scientific investigations; chemistry has been perhaps its greatest helper. Physiology, which is the basis of medicine, owes to chemical research its knowledge of the chemical processes going on in respiration and tissue nutrition. The chemistry of digestion, the processes whereby renal and skin excretions are effected, the processes of metabolism, all owe their elucidation to modern chemistry.

The phenomena of internal secretion are essentially chemical processes and offer a very wide and fertile field for further research. One of the most interesting discoveries of recent times was the isolation of the active principle of the internal secretion of the suprarenal gland. This substance, known as adrenaline, was first isolated in pure condition by Takamine. Its formula is  $C_9H_{13}NO_3$ ; it is 1-methyl-amino-ethanol-catechol. Its chemical and physical properties have been accurately determined, and its physiological action is quantitatively known. Adrenaline has been artificially synthesized, the synthetic product being known as suprarenin. The synthetic suprarenin is, however, less powerful in its physiological action than the natural adrenaline. Both possess the same chemical formula, but stereo-isomerically they differ, the synthetic product being the racemic modification of the natural laevo-rotatory compound. Recently a preparation of adrenaline has been synthesized which is laevo-rotatory and said to be of equal physiological value to the natural product.

This recalls Pasteur's early work and difficulties in connection with the tartaric acids. Stereo-isomerism appears to play a most important part in physiological action. The varieties of hyosine provide another striking example of this, the laevo variety being stated to be twice as active upon peripheral nerve endings as the inactive variety. The influence of stereo-isomerism on physiological action adds to the difficulties of the artificial synthesis of complicated compounds. Adrenaline is the only hormone that has been isolated in pure condition as a known chemical compound. What a wide field of research is still open to chemistry and biochemistry!

The vitamins, of which so much has been written the last few years, are known to play a most important part in nutrition. Their resistance to heat and methods of extraction are known, but none of them has yet been isolated, and their chemical constitution is unknown.

### MEDICINE'S DEBT TO CHEMICAL RESEARCH.

Only a few instances need be given of the recent developments in medicine which owe their discovery entirely to chemical research.

**Renal Disease.**—Chemical analyses of the urine have been of great value in determining the function of the kidneys in disease, but since the kidneys act by removing waste products from the blood it is obvious that the best criterion of renal function will be the estimation of the excretory products in the blood. During the last few years methods have been devised and perfected (Marshall, van Slyke, and others) whereby urea in the blood can be accurately estimated on 3 c.cm. of blood. The method depends on urease fermentation and estimation of the ammonia produced thereby. Similar microchemical processes have been devised whereby (1) the non-protein nitrogen in the blood can be determined (Kjeldahl's process on the filtrate after removal of protein); (2) estimation of creatinine in blood (picric acid colorimetric process); (3) estimation of uric acid in blood (a colorimetric process devised by Benedict, Folin, and Wu). These methods of blood analysis have added greatly to the knowledge of renal disease.

**Gastric Analyses after Test Meals.**—The application of chemical methods whereby the free and organically combined hydrochloric acid could be determined, and whereby organic acids could be estimated, have been of the utmost value in medical diagnosis. During the last few years fractional test meals have been used whereby titrations on very small quantities of gastric contents in the presence of colour indicators have been used for the determination of the hydrochloric acid present. The criticism of the fractional test meal method is that determinations based on titrations with colour indicators in the presence of organic acids are not always reliable.

**Jaundice and Liver Disease.**—Most valuable research on this subject has been recently carried out, and this has been based entirely upon Hijmaus van den Bergh's method of estimating the bilirubin in the serum from a small quantity of blood. The method is based on Ehrlich's discovery of the test for bilirubin.

### Insulin and Diabetes.

In 1922 Banting, Best, Macleod, and their co-workers succeeded in isolating insulin and obtaining a preparation suitable for clinical use, and in April, 1923, insulin, prepared under the supervision and authority of the Medical Research Council, was available for general use in this country. The discovery of insulin is a triumph achieved, after very many unsuccessful attempts, by able scientific workers to prepare the active principle of the internal secretion of the pancreas. Thus, in 1908, Zuelzer prepared from the pancreas an alcoholic extract which prevented the hyperglycaemia normally following an injection of adrenaline, and he used this preparation with some success on diabetic patients. His preparation was too toxic for repeated administration, owing probably to the presence of other substances with the active principle from the pancreas, and he failed to establish the therapeutic value of his preparation. The ultimate isolation of insulin by Banting and his co-workers is an excellent illustration of the value of careful and accurate scientific work along various lines in preparing the way for the reception of a great discovery. It is a good illustration of the value of what may be called "spade work" in scientific research.

During the last few years, owing to the advances made in physiology and chemical pathology, rapid and accurate clinical methods have been devised for the determination of sugar in the blood, for the estimation of acetone and diacetic acid in the blood and urine, and for the determination of the basal metabolism and respiratory quotient. The percentage of  $\text{CO}_2$  in the alveolar air can be clinically determined with facility, as also the carbon dioxide combining power of the blood. It is unnecessary for me to name the workers to whom we owe the perfection of these methods now in general use. It was by the application of these methods that the real efficacy of the insulin preparations was enabled to be at once tested, and their potency

proved beyond doubt. It will thus be seen that those workers to whom we owe the clinical biochemical methods enumerated above may claim an indirect share in the accomplishment of a great discovery. The successful preparation of insulin is of great value, not only in that a potent and efficient remedy has been discovered for a widespread and incurable disease, but it is also of value in illustrating the importance of patient scientific work along definite lines in paving the way for a new discovery. Just as a great victory in war is usually the culmination of steady and painstaking preparation with an object in view, so a great discovery in scientific research is not to be looked for by fortuitous investigations, but rather as the crowning point of steady and painstaking investigations along carefully thought out and definite lines.

### FORENSIC MEDICINE AND CHEMISTRY.

The perfection of methods of toxicological analysis, with which the name of Sir Thomas Stevenson must be associated, has greatly added to the advancement of toxicology. The application of newly discovered tests for alkaloidal and other poisons has been of great importance. (In the Palmer case (1855) the tests for strychnine were not known.)

In the toxicological detection of arsenic a very great advance followed the introduction of the electrolytic Marsh-Berzelius test. This has obviated the danger of error from chemical impurities in the reagents used, and has rendered possible the estimation of the arsenic in every organ of the body. The test was first applied for forensic purposes in the Seddon case (1911).

The method of determination of veronal and allied substances has been of great value in cases of narcotic poisoning of recent years.

In the analysis of blood stains the precipitin test, associated with the names of Uhlenhuth and Wassermann, has enabled the medico-legal expert to say not only that a stain is of blood, but the animal species of the blood can be in most cases accurately determined.

Toxicological analysis is usually complicated by the presence of organic decomposable matter, and requires experience and care in order that errors may be avoided. It is really a branch of applied chemistry.

### Forensic Evidence.

A very important function of the medical man and the chemist is the giving of evidence in courts of law, and also the assistance of commissions, departmental committees, and other public bodies who are conducting inquiries into subjects of chemical or medical nature. The inquiries may be of criminal or civil nature. Whichever it is, the function of the scientific witness is the same.

The giving of evidence by the scientific witness is one of the greatest privileges and honours which falls to his lot. It is important to realize that the true function of the expert witness is to assist the court of inquiry by his expert knowledge and experience. He should not be an *ex parte* witness and should be absolutely free from bias. This is supremely essential in criminal cases, but it is no less important that in civil cases the expert witness should be absolutely impartial.

The giving of scientific expert evidence is a responsibility not to be lightly undertaken. The statements of fact on which the inquiry is based should be very carefully considered and examined in a critical spirit. The scientific witness should refresh himself by the most careful study of the literature and scientific knowledge relating to the subject in question. If necessary he should conduct scientific experiments and investigations to elucidate any difficulties which may arise.

The expert witness should turn and turn over in his mind the subject on which he is asked to advise. He should unsparingly cross-examine himself on every aspect of the question. It is a great advantage that an expert witness should imagine himself to be in the position of judge or cross-examining counsel and try to regard the subject of inquiry from their point of view, as well as from the aspect of the counsel on whose side he is engaged. The success of an expert as a witness is much assisted by an appreciation of the psychological attitude of those who question him; this view of things will enable the scientific witness to anticipate the questions which are going to be put to him, and it will make him tolerant and charitable to the searching questions of the cross-examining counsel.

Before being called upon to give evidence the expert witness should express his opinion on the facts before him in a written report, and it is well that the reasons for the opinion should be concisely stated in the report. The opinions expressed in the report should be the unalterable views on which the expert has no doubt whatever. Any expressions of opinion on which there is any possibility of doubt should be omitted from the report.

In giving evidence the witness should remember that it is his duty to help the court by answering questions put to him in a clear, concise, fearless, and audible manner. In giving evidence in chief the answers should be brief and to the point. In cross-examination the answers should be as concise and clear as possible. Long explanations and evasions of a direct answer are likely to create a bad impression. A direct negative or affirmative should be given where possible; if this is not possible the reasons for the inability to give a direct answer should be clearly and courteously stated. Lengthy explanations and attempts to give lectures in the witness-box are apt to weaken the evidence and to raise points of which the cross-examining counsel will not fail to take advantage.

The duty of a witness, whether he is an expert or ordinary witness, is to answer questions put to him by those entitled to do so. He should avoid making any statements which are not answers to questions put. The expert witness should avoid giving any answers which are not absolutely free from ambiguity. Thus, for instance, if a question is a double or triple one, the witness should ask for the compound question to be suitably divided so that separate answers may be given to each. If statements from books or reports are put to him the expert witness will be wise to ask to see the work in question and to give his explanation of the bearing which any written statement has on the inquiry.

In conclusion, from a very lengthy experience as a forensic witness, I should like to express my very great appreciation of the courtesy and consideration which is invariably extended by members of the legal profession. It is the duty and privilege of the expert witness to assist justice by his experience and advice. It is his duty to ensure that his views are clearly put before the court and that not one jot or tittle should be withheld or left in doubt.

#### CONCLUSIONS.

The relationship between chemical research and medicine is so close that advances in each occur *pari passu*. With the development of bacteriology fifty years ago, and the impetus derived from its application to medicine, chemistry became somewhat overshadowed.

There have been clear signs of a great revival in the study of biochemistry during the last ten years, and at present medicine is looking towards chemistry and its applied branches for great and immediate advances.

Physical chemistry opens the gates to advances in an untrodden field of medicine and therapeutics. Already colloidal chemistry is supplying a host of new remedies possessing special attributes owing to their physical state.

In the solution by chemical methods of problems relating to disease or poisoning in the body, observations and analyses are often perforce conducted on very small quantities of material. It is for this reason that microchemical and colorimetric methods are frequently employed.

In chemistry as in medicine specialization of work has become necessary, since the fields of each are so vast. The interest taken by the various chemical societies in this country in biochemical problems, the rapid growth and influence of the Biochemical Society, and the attention given to biochemical problems by the various physiological and pathological societies, are all evidence of the intimate co-operation existing between chemistry and medicine.

Pure chemistry has as its religion absolute and scientific accuracy of work. It is necessary that this spirit of scientific accuracy should be the foundation of all those branches of chemistry applied to medicine. The close co-operation between pure chemistry and those branches applied to medical research is the best safeguard against any dangers from over-specialization. Biochemistry will be best advanced by the application of the principles of pure chemistry in its work.

It is to be hoped that biochemistry will more and more attract to its ranks men like Pasteur, who have ingrained in them the principles and methods of pure chemical science, and who will approach the biological problems in that spirit of critical judgement and of experimental investigation which is so essential for great work.

## CHRONIC PELVIC PAIN IN RELATION TO NEURASTHENIA.\*

BY

R. P. RANKEN LYLE, M.D.,

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF DUEHAM.

CHRONIC pelvic pain in relation to neurasthenia is, I think, a subject of very great importance; this is due to the fact that large numbers of unnecessary operations have been and are being performed for this condition, owing to the operator not recognizing the general condition of the patient and ascribing all the various symptoms that she complains of to some little pelvic abnormality, which could not in any way, even with the most vivid imagination, be rightfully attributed as the cause of her general condition. In other words, operations are being performed from an entirely wrong diagnosis. These operations are not altogether devoid of danger, as the statistics show; they subject the patients to the risk of serious complications later on, and even at the very best they accentuate the patient's sufferings and often drive her to seek medical advice elsewhere.

Of course, when cases of chronic pelvic pain are associated with definite physical signs, such as in pyosalpinx, there is generally no trouble in associating the pain with the physical signs, but such cases only form a small percentage of our patients. The largest percentage of patients who come to us complaining of chronic pelvic pain have generally nothing abnormal in the pelvis at all, or perhaps some minor condition, such as a mobile backward displacement of the uterus, which is frequently wrongly regarded as a cause of the pain.

The subject of neurasthenia is only gradually coming to be understood. About twenty years ago the diagnosis of neurasthenia was generally considered as tantamount to no diagnosis at all. Probably the best article that has been written on this subject, and one of the earliest articles, was written by Herman. He differentiated between the two extreme types of neurasthenia and described them with great accuracy: one type might be called the maniacal type, and the other the melancholic type. I am going to deal with the former type, because it is invariably associated with chronic pelvic pain. I hope, however, to be able to deal with the melancholic type at a future date, and to show how the vast majority of cases of descent of the pelvic floor are associated with it.

There have been many previous ideas as to the causation of pelvic pain in the absence of definite abnormal physical signs. It used very commonly to be ascribed to ovarian neuralgia, to prolapse of the ovary, to supposed adhesions, to supposed appendicitis, to mobile displacements of the uterus, and to varicocele of the pampiniform plexus; but all of these ideas are gradually becoming recognized to be erroneous, and some of them, especially ovarian neuralgia, are seldom if ever mentioned at the present day.

The previous methods of treatment of this condition depended on whether the case came under the view of a physician or a surgeon. The physician treated such cases by poultices, plasters, opiates, sedatives, hot vaginal douching, vaginal tampons, and numerous pessaries, all of which only aggravated the general condition, and the patient often became so bad that she had to be subjected to what used to be known as the Weir Mitchell treatment. This, in many instances, only made the patient a chronic confirmed invalid, and aggravated the condition by giving her ample time for her uneasy mind to dwell upon her numerous aches and pains. When it became evident to the physician that her mind was dwelling too much on her aches and pains, he prescribed asafoetida and valerian, for the purpose of distracting her attention to the smell of the medicine. Even at the present day crowds of such patients can be seen at a certain fashionable watering place, drinking water saturated with sulphuretted hydrogen in the hope that it may alleviate or cure their troubles.

\* A paper read before the Edinburgh Obstetrical Society, Wednesday, December 10th, 1924.

If, however, the patient came under the care of a surgeon, he, not recognizing the neurasthenic condition, performed all sorts of operations, which also only aggravated her mental and nervous condition, and in not a few instances her days were ended in an asylum.

Perhaps some will remember how common the removal of the ovaries was twenty-five years ago for ovarian neuralgia, until Herman spoke most strongly against it, and from that time the operation gradually commenced to die out. I think we are all now agreed that the removal of the ovaries in those cases was most highly detrimental to the patient's welfare. I have seen numerous chronic invalids who have stated that since their ovaries were removed they have not had a single day's health. Only last week I saw such a case, who appeared to me to be on the verge of insanity—a truly pathetic picture.

Immediately following that there came a great boom in operations for appendicitis, and if any patient happened to have a pain in the region of the right iliac fossa the diagnosis of appendicitis was usually made, and in many instances as the operation was being performed the appendix was found perfectly healthy. Then came such operations as ventral and vaginal fixation, but, on account of complications arising in subsequent pregnancies, vaginal fixation was soon abandoned, and ventral fixation or hysteropexy was not looked on altogether with undiluted favour. Then came various forms of suspension, and the Alexander-Adams operation, Gilliam's operation, and the Baldy-Webster operation; but all of these operations are fast being consigned to obscurity. We all remember, some years ago, how frequently nephropexy was performed in women suffering from pain slightly to the right of the umbilicus, or pain in the back, with all the same concomitant symptoms, such as dragging of the leg, headaches, etc., as are associated with the cases that I am at present describing, and the general surgeon can be heartily congratulated on the fact of having realized that nephropexy not only did not benefit them, but actually made them much worse; consequently, so far as I know, this operation is now practically abandoned.

How frequently one comes across a patient, who has had one of these operations, and who says that she is worse than ever, that the operation had only aggravated her condition, and that she wishes she had never submitted to it. With regard to ventral fixation or hysteropexy, an additional trouble is added in case of a future gestation. I have seen several cases where parturition was complicated by it, and at least two deaths in labour as the indirect result of this unnecessary operation. With regard to the Alexander-Adams operation, Herman spoke strongly against it, and I think his views have been confirmed by many observers since his time. Gilliam's operation and the Baldy-Webster operation are in a similar category. To think that a mobile displacement of the normal uterus could cause any trouble necessitating any of these operations is a pure delusion.

In 1923 I paid a visit to America, and had a long conversation with Dr. Hall of St. Louis, the leading gynaecologist in that great city, and head of the St. Louis Maternity Hospital; he entirely concurred with these views. Such views are also held by the leading gynaecologists in Sweden and by many first-class teachers in London, and I would refer you to the valuable paper read before the North of England Obstetrical and Gynaecological Society by Dr. Archibald Donald on the treatment of mobile backward displacement of the uterus (BRITISH MEDICAL JOURNAL, December 13th, 1924, p. 1087). At the Annual Meeting of the British Medical Association in 1921 I expressed similar views at the Obstetrical and Gynaecological Section, and I had practically the unanimous support of the meeting.

I now wish to describe briefly the position of this question at the present day, and for my purpose will roughly classify pelvic pains generally into three classes:

- (a) Cases due to inflammatory tumours or neoplasms.
- (b) Cases due to urinary troubles.
- (c) Cases associated with chronic dilatation or neuralgia of the great intestine or caecum.

It is with the last class that I wish particularly to deal, and it is this class that is so invariably associated more or less with the symptoms of maniacal neurasthenia. In such cases the patient complains of pain in the right iliac fossa over the caecum, or in the left side of the lower abdomen over the descending colon. In rare instances the pain will follow the line of the transverse colon, or may perhaps be found a little to the right of the umbilicus.

In nearly all these cases the characteristics of the pain are more or less similar. The patient describes it as a dull gnawing or aching pain in the right or left side, which often passes round to the back or down the thighs, causing numbness or dragging of the leg on the affected side. Bimanual examination will reveal nothing abnormal, or perhaps in a few cases a mobile displacement of the uterus, which I regard as in no way associated with this condition, but merely as an accidental position of the uterus which causes no symptoms. If the patient is asked whether she suffers from headaches, sleeplessness, "weak turns," palpitation, and all the general symptoms of neurasthenia, they will, as a rule, all be present. Not only that, but in most cases there will be no difficulty in observing certain facial characteristics, which are also a very good guide to the diagnosis. These characteristics are a want of the normal expression of the face, the angles of the mouth drawn slightly backwards or downwards, and a marked dilatation of the pupils.

As to the cause of the condition, we all know that probably the most common trouble amongst all women is constipation, intestinal stasis, or some intestinal irregularity; if the patient's general nervous system is normal the constipation is seldom associated with pain, but when for any reason her nervous system becomes irritable, or her nervous resistance to pain falls below normal, she is bound to feel pain first in whatever part of her body is most liable to irritation, and that part of her body is the great intestine and caecum. Then her mind is fixed on the situation of this pain, and a vicious circle is formed. The patient commences to worry about the pain, her nervous resistance is still further lowered, the pain becomes gradually worse, and before very long she goes to someone to obtain medical advice.

If by chance such a patient happens to have a mobile backward displacement of the uterus, and an operation is suggested and performed with a view to placing the uterus in a position of anteversion, it is quite possible that the mental satisfaction to the patient of having something radical done, and the three weeks' rest in bed, together with a complete change of atmosphere, will ensure temporary benefit; but it would be a great mistake to think that the actual details of the operation or the placing of the uterus in an anteverted position could do her any good.

In reading the accounts of the results of these operations I have noted the unanimity of the operators in claiming success for them from the fact that the uterus remains in an anteverted position even after a subsequent gestation, and not one single word as to whether the patient's symptoms are alleviated or cured, which, I think, is of primary importance. What difference can it make to the patient whether the uterus is anteverted or retroverted so long as her headaches, her pains, and her numerous symptoms remain still unrelieved?

In many cases a careful examination of the pelvis, and an assurance that she has got no pelvic disease and that the condition is merely due to worry or nervousness or constipation, will make her feel quite well. In other cases a mixture of potassium bromide and magnesium sulphate, together with fresh air and outdoor exercise, telling her not to tire or fatigue herself in any way and to stop worrying, will generally be sufficient treatment.

I have specially considered this subject for many years, and am fully convinced that the old methods of treatment and have spoken of are not only detrimental to the general condition but detrimental to the patient. I have also been greatly impressed on innumerable occasions by the ease with which a mere assurance to the patient that she has got no pelvic disease will not only settle her mind, but will make her quite well again.

## MUSCULAR EXERCISE IN DIABETES MELLITUS.

BY

K. S. HETZEL, M.B., B.S. ADELAIDE,  
M.R.C.P. LOND.,

ASSISTANT IN THE MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL.

In conjunction with Mr. C. N. H. Long, M.Sc., experiments are in progress on the effect of muscular exercise in patients suffering from diabetes mellitus. We hope shortly to publish the results in full dealing with lactic acid, acidosis, and the respiratory metabolism. This preliminary communication on the blood sugar and urinary changes brought about by exercise is written more from the clinical standpoint.

Allen and his followers have insisted that in the treatment of patients suffering from diabetes mellitus it is beneficial for them during the time of their dietetic adjustment and subsequently to take moderate exercise and not to remain in bed for prolonged periods. The present experiments show that in a diabetic whose diet contains a moderate proportion of carbohydrate and who receives an adequate supply of insulin the effect of exercise is beneficial, rapidly lowering the blood glucose to a normal level and diminishing the production and therefore the excretion of ketones and so rendering tissue metabolism more complete. But in a patient even with adequate carbohydrate foodstuff or carbohydrate stores whose diabetes is moderately severe and who is without sufficient insulin, endogenous or exogenous, exercise produces little or no effect on blood glucose and ketosis is increased.

The patients who are the subjects of these experiments had been treated for some time previous to the experiments by dietetic restriction and adjustment with insulin, and they are now continuing their ordinary routine life.

The exercise which has been done is that of "standing running" in which the subject doubles rapidly on his toes with the elbows flexed and the arms drawn to the side of the chest, but he does not move forward and he maintains his position on about one to two square feet of floor space in the laboratory, drawing the knees well up. The number of steps a minute is noted, the patient keeping time with a metronome which is set to a certain rate; in this way the subject keeps up the rate of exercise for the stipulated time. The exercise done—for instance, 156 steps per minute—is only moderate, and a normal subject can readily do it for the time over which these patients were exercised, and with no great fatigue. By "all out" exercise is meant that the subject doubles as rapidly as he can so as just to last out the time, at the end of which he is "done." Samples of blood and urine are taken at intervals before and after the exercise. A rough estimate of the amount of urinary ketones has been made by the depth of the colour which is attained in one minute by the Rothera or sodium nitro-prusside test. These are designated  $\pm$  for a faint trace,  $+$  trace,  $++$  and  $+++$  for deeper colorations. All the samples of urine are examined at the same time and set side by side so as to get the comparative variation in colour produced.

**CASE I.**  
Male, aged 36; decorator. Weight 10 st. 10 lb. Diet 2,090 calories: Carbohydrate 69 grams, protein 77 grams, fat 167 grams. Insulin 30 units a day, given in two doses, of 20 and 10 units each. This patient had received insulin for seven weeks and he had been discharged from hospital on the above diet for three weeks when the first experiments—for example, experiments B and E—were done. The experiments were made at intervals over a period of five and a half months. This man leads an active life and he feels and looks a fit man.

**EXPERIMENT A.—Control for ordinary fall of blood sugar without exercise. Without insulin for thirteen hours—last meal two hours previously.**

Time.		Blood Sugar per Cent.	Urine.	
			Glucose.	Ketones.
10 a.m.	Resting	0.215	0.06%	$\pm$

Experiment A is shown graphically by curve A in Fig. 1. Fig. 1 also demonstrates the results of Experiments B and E.

**CASE II.**

Male, aged 21; clerk. Weight 9 st. 6 lb. Diet 1,840 calories: Carbohydrate 52 grams, protein 92 grams, fat 140 grams. Insulin 50 units a day, in three doses of 20, 10, and 20 units each. Insulin had been given for twelve months before the experiments began. Three months before these experiments the diet and the insulin were increased to the above values. This subject is a severe case, and, although not as fit as Case I, he is active and he is able to do the exercise briskly.

In the diabetic patient at rest the hyperglycaemia due to ingestion of food tends to decrease slowly. This fall in blood sugar is slower the more diabetic the patient is—that is, the less endogenous insulin there is present capable of metabolizing the glucose. This gradually decreasing hyperglycaemia is demonstrated in the ordinary glucose tolerance curves.

Fig. 1 represents the results of Experiment A, in which the blood sugar falls slowly and continuously to the normal and the ketosis, which is slight, is not affected. The effect of exercise is to lower this hyperglycaemia very rapidly to a normal blood sugar level ranging between 0.07 and 0.10 per cent. When the blood sugar is low to begin with, and within

FIG. 1.—The gradual and continuous fall in the blood sugar to nearly normal during three hours in the resting diabetic patient, without insulin for thirteen hours, and having had food two hours previously. A trace of ketosis is maintained throughout. Curves marked A are the results of Experiment A, Case I. The effect of the same exercise (three and a half minutes "standing running" at 210 steps per minute) on the blood sugar and ketosis in the same subject (Case I) when insulin had been given two and a half hours before — (1 in square) and seventeen hours previously — (2 in circle). The curves marked with the same numerals correspond. The curves with definite points are the blood sugar curves, and the others represent the urinary ketones. Exercise is started at zero time.

the normal range of 0.07 to 0.10 per cent., exercise has little or no effect on it. If ketones are present in the urine before the muscular exercise they are always absent or diminished in amount after the exercise, even when the blood sugar is low at the start, provided insulin has been administered not many hours previously.

The less severe cases of diabetes show these results—that is, a rapid fall in the blood sugar and a decrease in ketosis up to twenty-four hours since the last administration of insulin; but in the severe diabetic this result is only shown when insulin has been administered within the last fourteen to twenty hours. After the lapse of twenty-four hours in the severe diabetic, the production of endogenous insulin being smaller, very little or no effect is noticed on the concentration of glucose in the blood, as is shown in Experiments T, U, and V. In these circumstances too the ketosis is increased, showing that tissue metabolism is less perfect, and especially that of carbohydrate, for only in the perfect and complete metabolism of carbohydrate is the katabolism of fats perfect. The excretion of glucose in the urine is increased also, presumably owing to increased blood flow and increased excretion by the kidney after the exercise.

Curve A, Fig. 2, represents the patient's glucose tolerance eight weeks before Experiment H. The quantity of insulin he is now taking is the same as when he was discharged from hospital, so he has not gained tolerance to any marked degree.

Curve B, Fig. 2, represents this patient's glucose toler-

FIG. 2.—The glucose tolerance of Case I, with 40 grams of glucose before treatment with insulin was begun (Curve A), and seven months later after continuous insulin treatment (Curve B). See text. Curve A, after forty hours' starvation. Curve B, no insulin for sixteen hours; last meal five hours before the glucose was given.

ance with the same quantity of glucose seven months later. The configuration of the curves approximate closely, the difference in absolute blood sugar percentages being due to the fact that when Curve A was taken the patient's urine was not sugar-free and so the whole curve was displaced to a higher level. In the case of Curve B the patient's initial blood sugar was at a lower level and he was not passing sugar in his urine when the 40 grains of glucose were administered. So from the glucose tolerance tests and from the fact that his daily quantity of insulin has not been altered one would conclude that there had been little or no gain in carbohydrate tolerance.

In Experiment H the subject had had no insulin for sixteen hours when the 30 grams of glucose were given, so there can be little doubt that the exercise prevented glycosuria, and more than this, the exercise caused a rapid fall in the blood sugar. Most of the glucose must have been metabolized or rendered non-reducing as the result of insulin produced by the patient's pancreas consequent on exercise and increased blood flow, and probably to some extent by insulin previously stored in the tissues.

Hence for practical purposes we may state that in the mild and less severe diabetic with insulin moderate exercise has a beneficial effect by increasing tissue metabolism, burning glycogen, depleting the blood sugar, and more completely

transformation of the glycogen stores to glucose as the result of muscular exercise. A fall in the blood sugar concentration on exercise doubtless occurs in the normal healthy man, but the changes are not readily demonstrable, because of the small range over which the normal glycaemia fluctuates, any change being relatively small. However, when the range of glycaemia is increased, as in the diabetic, this fall in blood glucose on muscular exercise is more readily demonstrated.

#### CONCLUSIONS.

From these observations we might advance certain theoretical considerations. As the result of the muscular exercise a certain amount of glycogen must be katabolized in the muscles and a vacuum created which would necessitate a more rapid impouring from the blood of glucose to make this good. Already there is pouring into the blood glucose derived from other glycogen stores—for example, the liver—but this influx of glucose is not accelerated unless the blood sugar falls to below 0.070 per cent., and so the blood sugar would fall from exercise to this level. When the blood sugar at the beginning of exercise is low, as the same exercise is done the transformation of glycogen in the muscles must be at least equal to the transformation in circumstances when the blood sugar is relatively higher, and so the vacuum in the muscles must be made good at the expense of the blood sugar; but the blood sugar itself is replenished concurrently from the glycogen stores, but the glucose does not flow in in excess and the blood sugar remains at its initial low level. This would postulate a delicate balance between blood sugar and glycogen stores, the transformation of the latter to glucose not being in excess of its normal rate unless the blood sugar falls below 0.07 per cent.

Our conception of hypoglycaemia occurring from an excessive amount of insulin is that the blood is being depleted of its glucose more rapidly than the glycogen stores can be transformed into glucose, and so this latter process cannot keep pace with the former, and the blood sugar falls to the hypoglycaemic level and below it.

This hypothesis would hold good when there was an adequate quantity of insulin in the tissues. But when there is inadequate insulin present in the tissues there is no increased depletion in the glucose concentration of the blood, and the production of ketones is increased on exercise. Since the exercise is done just as efficiently the muscle metabolism must be as good, and just as much energy is needed for an exercise of equal length and rapidity to that in circumstances where insulin has been given shortly before. However, in the absence of adequate insulin the loss of glycogen or like products in the muscle tissue is not made good by the blood in excess of the amount which would be pouring into them when these structures were at rest, and so the blood sugar percentage does not fall more rapidly than it would have done had the subject remained at rest. Again, in the absence of sufficient insulin carbohydrate metabolism is less perfect, and so there is an increase of ketone bodies in the urine from the incomplete combustion of fats.

Hence insulin is essentially associated with the metabolic processes in the muscles, but apparently it is not necessary for the transformation of glycogen to lactic acid in the contraction of muscle, but the transformation of glucose into glycogen precursors and the intrinsic metabolic processes of muscle depend on its presence.

#### SUMMARY.

1. Muscular exercise in patients suffering from diabetes mellitus depletes the blood glucose provided there is an adequate supply of insulin in the tissues.
2. The more perfect and complete tissue metabolism is demonstrated by the disappearance of ketones from the urine under these conditions.
3. As the result of exercise the blood sugar tends to fall rapidly to between 0.07 and 0.10 per cent., but it does not become lowered further.
4. No hypoglycaemic reactions have occurred on exercise even if the initial blood sugar was as low as 0.07 per cent.
5. Muscular exercise does not tend to cause acidosis provided there are adequate carbohydrate and insulin for its transformation.

FIG. 3.—The effect of muscular exercise on the blood sugar and ketosis in the same patient (Case 11) when insulin had been administered six hours before (1 in square); not for eleven hours (2 in circle); and when he was without insulin for twenty-two hours (3 in triangle). All curves are read from left to right.

burning fats. In the severer case with insulin the same beneficial effect is noticed with exercise, but without adequate insulin exercise has no depleting effect on the blood sugar, and it increases the production of ketones. It amounts to the fact that with insulin most cases of diabetes can be rendered nearly normal as regards the tissue metabolism, but the severer cases depend much more on adequate quantities of insulin.

It was definitely recognized before the introduction of insulin that excessive exercise was a potent factor in causing diabetic coma in patients suffering from diabetes mellitus, and the explanation is readily understood when it is realized that the energy is produced at the expense of the incomplete tissue metabolism in the absence of a sufficient insulin supply, thus increasing the production of ketone bodies and resulting in acidosis and coma. Experiment V demonstrates this. The likelihood of acidosis and coma supervening as the result of exercise in the diabetic is small provided there are adequate supplies of carbohydrate or material capable of being readily converted to such and a sufficient supply of insulin.

These patients have been able to do the exercise without undue fatigue, and no difference has been noticed by them either in the nature of muscular stiffness or fatigue with and without insulin. No hypoglycaemic reactions have occurred even in such experiments as P and Q, where the blood sugar was low before the exercise, so even though the blood sugar is depleted there is apparently no check in

6. Exercise in patients without sufficient insulin, endogenous or exogenous, causes no change in the concentration of glucose in the blood, but markedly increases the production of ketone bodies, with resultant acidosis and the likelihood of the supervention of a diabetic coma.

7. An hypothesis for the action of insulin is suggested from these experiments.

## SOME OBSERVATIONS ON BLACKWATER FEVER.

BY

ERNEST P. CARMODY, M.B.E., M.R.C.S., L.R.C.P.,  
DISTRICT SURGEON, BINDURA, SOUTHERN RHODESIA.

"I am of opinion that our first duty is to inquire whether a thing be or be not, before asking wherefore it is."—HARVEY.

ENCOURAGED by my success in the treatment of blackwater fever, I feel justified in publishing my observations on 36 consecutive cases, and an account of the method of treatment I have followed.

The district of Bindura, situated about the middle of the Mazoe Valley, which runs from west to east for some sixty miles, has a somewhat scattered European population of 350. The district is traversed by the Salisbury-Shamva branch railway. Bindura station, 70 miles north-east of Salisbury, and 1,730 miles distant from Capetown, lies at an elevation of 3,737 feet above sea-level, and is the most northerly point on the railway system of Southern Rhodesia.

Bindura has the reputation of being the worst blackwater district in the country. The average mortality from blackwater fever in Southern Rhodesia, taken over a period of twenty years, is, according to the medical director's report for the year 1921, 20 per cent.

Since my arrival here in February, 1921, I have studied the local history of the disease and its treatment, both by the Roman Catholic sisters—who were the earliest nurses in the country—and the early settlers. It appears that they considered it imperative that blackwater cases should not be moved, but nursed on the spot where the disease was developed.

Blackwater fever may be defined as an acute non-infective disease associated with characteristic dark urine and grave constitutional disturbances. It is a condition affecting Europeans, very rarely natives, occurring at all ages, and most prevalent in males; it is consequent on chronic subtertian malaria, even though there be no definite paroxysms of fever.

I consider that blackwater fever should be regarded as para-malaria, and that its possible cause is a chronic anaemia, fulminated by a sudden lowering of the vitality from any cause; this leads to a temporary rapid hypotonic osmotic condition of the blood plasma, and consequent bursting of the red blood corpuscles.

My conclusions are based on my successful application, in the early stages of the disease, of normal saline injected subcutaneously, and sodium bicarbonate administered by the mouth. My belief is confirmed by the views expressed by various medical writers, including Manson (*Tropical Diseases*, seventh edition), of the value of subcutaneous and intravenous hypertonic and isotonic salt solutions. Further corroborative evidence lies in the fact that chronic malaria is associated with profuse sweating and consequent loss of salt.

### SYMPTOMS.

*Promonitory.*—A relatively large number of patients complain of severe abdominal pain with constipation, about twenty-four to forty-eight hours before the onset of blackwater fever.

The onset is usually characterized by the passing of six to ten ounces of very dark urine, in colour and frothiness like porter, but when viewed in a thin layer of a dark red colour; this is the first warning to the patient that he has blackwater fever, although he may not have been feeling very well, and has assumed the onset of malaria. The patient looks ill and the pulse is rapid, but pyrexia is by no means a feature of the disease in all cases. Headache,

loin-ache, and nausea are usually present, and a rigor may occur. Jaundice in a slight degree may be present before the onset of blackwater, but usually it comes on some hours after, and grows very profound if the patient is moved or shaken. The liver and spleen are nearly always palpably enlarged and the latter tender.

### Danger of Moving.

Mortality in cases who have been moved, even for a short distance, is very much higher than in those who have not been moved. Before I realized this two patients I moved with the utmost care, and only for a short distance, became suddenly intensely yellow and very collapsed within a few minutes of being lifted, and subsequently had two or three severe relapses in the following five or six days. One case, a slight one, moved ten days after the onset and seven days after the water was quite clear, was run slowly by car for a distance of five miles over a rather rough road, and immediately developed one of the severest attacks of blackwater I have seen. Another recent case went by train to Capetown twenty-seven days after the onset, and had a relapse.

*Complications.*—Acute nephritis, scanty urine, and complete suppression are perhaps the most trying and dangerous complications one has to be on the look-out for. Abdominal complications seem to figure largely: the pain is of a gripping character, and seems to be referred to the colon, and in most cases I have seen there has been obstinate constipation. In one case this appeared to lead to lighting up an old appendix, and in another to intussusception; in each of these cases the patient was too collapsed for operation to be urged. Two of my cases developed bronchopneumonia, and this, I think, was due to getting uncovered whilst hot and sweating profusely.

The diagnosis as a rule should present no difficulty in a patient who has lived in a country where malignant tertian malaria is prevalent, and whose first symptom of real illness is the characteristic urine.

### TREATMENT.

Prophylactic treatment consists in protection from mosquitos (and therefore malarial infection), early diagnosis, especially in incipient cases of malaria, and efficient quinine treatment over a sufficiently long period, and maintenance of good general health by means of good food and housing, the removal of all scrub near dwellings, and the draining or protection of all pools of water wherein mosquitos might breed. The successful treatment of blackwater fever depends on taking care not to move or shake the patient in any way. Therefore, if the patient is not near any dwelling, every effort should be made to bring a bed to him and erect a shelter over him.

Having got the patient to bed and well covered, I now, as a routine, immediately inject subcutaneously 5 to 10 ounces of normal saline, and repeat it if necessary. With this I find the urine, even in severe cases, clears up more quickly, sometimes in a few hours, whilst the jaundice and the constitutional symptoms are less marked. I also give from 1/2 to 1 ounce of magnesium sulphate at the beginning. This is probably beneficial from its depletive effects.

As 20 grains of sodium bicarbonate hourly is found to be beneficial in these cases, and as nausea and restlessness are nearly always troublesome features, I generally give a mixture such as the following:

R. Sodii bicarb. ....	...	...	...	gr. xx
Bismuth carb. ....	...	...	...	gr. x
Tr. chlorof. et morph. co. ....	...	...	...	℥ v

S. To be taken every hour in 5 oz. of water.

I have found vomiting less severe since giving up "Sternberg's mixture"; this, I think, is due to the fact that the mixture contains mercury perchloride. Abdominal or loin pains are best treated with hot-water bottles or antiphlogistine.

As a rule I do not prescribe quinine, but see no reason why it should not be given, and when symptoms of acute malaria have been present I have given it with good results; but it is best administered by intramuscular injection.

tion owing to its tendency to cause vomiting when taken by the mouth.

Large quantities of fluids should be given (water, barley water, etc.). Lactogen, slightly sweetened, has been well tolerated where there has been much nausea, and Benger's food has also been easily taken.

The patient should be kept in bed for at least fourteen days even in the mildest cases. It is owing to patients failing to realize the importance of this that the prognosis of a mild case is so bad.

## RESULTS.

Since assuming the post of district surgeon, Bindura, I have seen 36 cases of blackwater fever (29 males and 7 females); 53 recovered and 3 died. The percentage of mortality was thus 8.33. All the deaths occurred in males. Only one was actually due to blackwater fever, and in that one my warning not to move the patient had been disregarded.

## Deaths.

*Case 1.*—A middle-aged man, living temporarily in a tent, developed blackwater fever. On the day of onset I attended him, and found that he did not present any alarming symptoms. He was put on the treatment I have mentioned, and instructions as to diet were given to his wife. She was also warned not to allow him to be moved. On the third day of the disease I had a message stating that his water was now quite clear and that he was much better. On the morning of the fourth day I received a very urgent message saying that the patient had been moved, for better nursing, to a cottage a quarter of a mile away, and was then in an extremely critical condition. I found the patient quite collapsed and very yellow. All attempts to improve matters by the use of hot-water bottles, subcutaneous and rectal saline, injections of camphor, strychnine, and pituitary extract, failed to produce any improvement, and he died twenty-seven hours after having been moved.

*Case 2.*—A middle-aged man who had no blackwater for ten days, and who had a history of a severe kick in the epigastrium from a mule three months before, developed what clinically appeared to be intussusception and died. He had complete stoppage, passed blood per anum, and had a well defined sausage-shaped tumour in the region of the transverse colon; the diagnosis, therefore, was probably correct. Operation was refused, and I did not urge it owing to the weak state of the patient; the relatives refused a post-mortem examination.

*Case 3.*—A young man developed severe blackwater fever, with scanty urine and retention, which necessitated catheterization during the whole of his illness. The urine became clear in two days, when bronchopneumonia developed; this cleared up in four days and the patient's condition seemed most hopeful. The patient then developed a very severe attack of mumps, and after another twenty-four hours an old appendicitis of five years' standing lit up. The patient was too ill to stand an operation, and died twenty-four hours later.

## CONCLUSIONS.

A case of blackwater fever should never be moved if it can be avoided, and then only with the greatest care and for the shortest possible distance.

No case should be moved for at least fourteen days after the onset, however slight the case may be.

If possible a trained nurse should be obtained to see that the treatment is properly carried out.

If subcutaneous saline injections are given at once the urine will clear up more quickly.

I feel confident that quinine does not cause this disease, or even act as the fulminant, and think the reason this idea has been entertained is that, the premonitory symptoms being indistinguishable from malaria, quinine is taken, and the onset of blackwater is credited to it.

That blackwater fever is undoubtedly due to malignant tertian malaria has been conclusively proved by Professor J. G. Thomson of the London School of Tropical Medicine during his recent researches in Rhodesia.

The prevention of malaria, and therefore of blackwater, lies in the hands of the colonists, if they will only take the extremely valuable advice published for their benefit by Dr. A. M. Fleming, the medical director for Southern Rhodesia.

## CONTACT CASES OF LEPROSY IN THE BRITISH ISLES.

BY  
J. M. H. MACLEOD, M.D., F.R.C.P.,  
PHYSICIAN FOR DISEASES OF THE SKIN, CHAIRING CROSS HOSPITAL;  
HONORARY MEDICAL ADVISER TO THE ST. GILES'S HOMES  
FOR BRITISH LEPEES.

At a recent meeting of the Dermatological Section of the Royal Society of Medicine a contact case of leprosy was shown in a boy, aged 14, who was born in England, had never been abroad, and who contracted the disease from his father, a leper, who died four years ago. This is the first case which has been exhibited at the Section in which the disease was contracted in this country.

Within the last few years I have seen three other similar cases, and in view of the impression, not only among laymen but even among certain members of the medical profession, that leprosy in this country is either non-contagious, or its contagiousity is so slight as to be negligible, I have considered it advisable to put these cases briefly on record.

## CASE I.

A boy, aged 12, with nodular leprosy, was born in a southern county in Ireland, and was never out of Ireland until he was brought over to London for advice with regard to his disease. His father was a Russian, who had emigrated to Ireland, and who was in comparatively poor circumstances. When I saw the father he was suffering from nodular leprosy in an advanced stage, and had had the disease when he reached Ireland. As far as I could ascertain, the mother was not infected.

## CASE II.

A boy, aged 15, was admitted to the St. Giles's Homes for British Lepers in 1920, suffering from nodular leprosy, with ulcerated lesions. He was born in a town in Lancashire and had never been out of England. His parents were healthy and had from British Guiana, bringing an elder son who had nodular leprosy. The boy was born a fortnight after their arrival in England. During his childhood he had been in close association with his infected brother, with whom he had slept for five years, and from whom he contracted the disease. He died in the St. Giles's Homes after being there seven months, two years after the death of his leper brother.

## CASE III.

A married woman, born in Belgium, who suffered from leprosy of the mixed type, with both nodular and anaesthetic lesions. She was married in England and had lived here since then. She contracted the disease from her husband, who had nodular leprosy, and died in the St. Giles's Homes in 1916. Down to the time of her husband's admission to the Homes, she had taken no precautions to avoid infection, and had lived with him.

It is only comparatively of late years that the contagiousity of leprosy has been recognized, and it was not until 1897, at the first Leprosy Congress held in Berlin, that leprosy was definitely agreed to be a contagious disease, and resolutions were passed recommending compulsory notification and segregation. Since then numerous instances have been recorded of the transmission of leprosy by contact in countries where the disease prevails.

In Great Britain, largely owing to good hygienic conditions, leprosy has come to be a rarity, though at one time it was common, and the cases which exist here, with few exceptions, are exotic lepers who have come home from different parts of the empire where they had become infected with the disease.

The last place where a leper settlement of any importance existed in this country was in the Shetland Islands. There the disease seemed to have been rife, possibly because the natives were of Scandinavian origin, and were in more or less frequent communication with Norway and Iceland, where leprosy was prevalent. The value of segregation was early appreciated by the Shetlanders, and several centuries ago a leper colony was established in the island of Papa Stour, to which all suspected cases were sent. This is a remote island situated to the west of the Shetland group, and separated from the mainland by a stormy sound, which effectively isolates it in anything but fine weather. The last case of leprosy in Papa Stour—as far as I have been able to ascertain—died more than a century ago, and the

disease seems to have been exterminated there, probably on account of isolation and acquired immunity. At the present time the natives of the island are a hardy race, and show no trace of the scourge which prevailed amongst their ancestors, in spite of the fact that in winter their diet consists largely of dried, partially cured, and imperfectly cooked fish, a diet which was once believed to be responsible for the propagation of leprosy.

The experience in Papa Stour cannot but suggest that an island is the ideal site for a leper colony, and should it be found necessary to adopt measures of segregation here it might be possible to find some such island where a colony could be established.

The contact cases here recorded show the danger of belittling the contagiousity of the disease in this country, and of gainsaying the risk connected with intimate association with lepers; it may not be amiss to quote the resolutions of the second Leprosy Congress at Bergen in 1909—namely:

(1) "That leprosy is a disease that is contagious from man to man, whatever may be the method by which this contagion is effected."

(2) "That every country, in whatever latitude it is situated, is within the range of possible infection by leprosy, and may, therefore, usefully undertake measures to protect itself."

By means of a modified segregation, which was introduced in Norway in 1885, the number of cases was reduced in twenty years by about 50 per cent., and similar results have followed methods of isolation in Iceland and other countries. It does not seem inopportune at the moment to reconsider the advisability of putting our own house more in order, lest further cases should occur.

## A CASE OF MYASTHENIA GRAVIS.

BY

A. H. DOUTHWAITE, M.D., M.R.C.P.LOND.,  
WORTHING.

THIS case, I think, merits publication because the disease is comparatively rare, and the case also presents certain uncommon features.

A man, aged 57, sought my advice in March, 1924, on account of choking attacks occurring towards the end of meals. He had one healthy child. His mother had died of diabetes and his father of rectal carcinoma. Apart from scarlet fever at the age of 8 his health had always been good.

### History of Illness.

In 1913 he noticed that on tapping the extensor surface of either forearm or thigh the underlying muscle rose up in a wheel. His eyes happened to be examined at this time on account of errors of refraction; no ophthalmoplegia was then present. In 1914 he had a transient attack of abdominal pain and nausea accompanied by bilateral ptosis. This was attributed to his having eaten bad fish. Later in this year the muscles of the thigh and gluteal regions felt stiff and an unusual effort was required to rise from a stooping posture. Transitory diplopia also occurred about this time.

From then until May, 1923, the patient felt well, but the irritability of his muscles persisted. Since 1923 he had had frequent attacks of diplopia, which at first lasted from one to three days. From January, 1924, the condition became permanent, but was always less noticeable in the early morning. In March he noticed weakness of the jaw towards the end of a meal, and found that if he assisted it with his hand he was unable to close his mouth for half an hour afterwards. Being informed that he was suffering from a nervous breakdown associated with high blood pressure, he was advised to go to the seaside. His condition here became steadily worse, and marked ptosis in both eyes developed. For this he wore glasses, but found that the more he attempted to keep his eyes open the more complete was their closure. On the evening of March 27th fluid suddenly regurgitated through his nose whilst he was drinking, and a choking attack ensued.

### Condition on Examination.

When giving me the above history a remarkable change passed over him. Whereas at the commencement of the recital his voice was clear and strong, yet, as he talked, a nasal twang developed to a pronounced degree. The forehead, previously wrinkled, became smooth, and bilateral ptosis developed coincidentally. From time to time he stopped to support his jaw, then with a further effort struggled to the completion of the sentence. The main points discovered on examination were:

1. Pronounced hippus when a light was thrown on the eye.
2. Normal reflexes and sensations.
3. Blood pressure 162 and 105.
4. All except the muscular system normal. A skiagram of the chest revealed no suggestion of thymic shadow.
5. Muscular system: Weak right external rectus. Ptosis, which became more pronounced if the patient made a sustained effort to look upwards. Inability to roll r's when speaking, and to whistle. The masseters were rapidly fatigued by faradism, recovered after rest, and were again fatigued after the passage of the current for one minute forty seconds. They were then capable of weak voluntary movement and of contraction to the galvanic current. The "nasal smile" or "myasthenic snarl" was exhibited in an attempt to smile after conversation. The upper lip was drawn upwards in the effort, movement at the corners of the mouth being absent. Movement of the soft palate was defective, with slight deviation to the right. No weakness of the limb muscles was demonstrable, but they all showed the remarkable excitability to direct mechanical stimulation already referred to. This was chiefly marked in the extensors, a tap of the finger producing a wheel-like swelling of the muscle, which persisted in one case for three minutes. The reaction was precisely such as one finds in Thomson's disease, of which, however, there was no further sign.

### Choking Attack.

On the evening of April 19th I received an urgent summons as the patient was choking. I found him in a prostrate condition, filled with fear of impending death. The respiration was both stertorous and stridulous, the soft palate flapping to and fro with each breath. At the time it was impossible to examine the condition of the vocal cords, but on the following day a definite weakness of abduction could be detected. Apparently, previous to this attack, he had been talking more than was his wont, but the actual onset was precipitated by his taking some bismuth. Feeling the powder cling to the back of his throat, he made violent but largely ineffectual efforts to clear it, thus rapidly exhausting the pharyngeal muscles. Rhonchi and râles could be heard over both lungs at this time, and the patient complained of inability to "clear his chest." The condition improved during the following day, and in thirty-six hours he suddenly coughed up ten ounces of viscid mucoid sputum, expressing himself much relieved thereby.

### Treatment.

Treatment was mainly directed towards securing as complete rest as possible for the affected muscles. Visitors were forbidden. All food was minced so as to reduce mastication to a minimum. Both eyes were covered by shades for the greater part of the day. The masseters and larynx were daily subjected to diathermy, which appeared to produce a definite amelioration of the condition. Strychnine was administered by the mouth.

Gradual improvement followed, so that when last seen in June there had been no further choking attacks; nasal intonation of the voice was very slight; diplopia was often absent during the greater part of the day. The patient was thus able to return home and resume light work.

Presumably the ultimate prognosis is thoroughly bad.

The main point of interest in this case is to be found in the muscular excitability to mechanical stimulation. Those muscles which were clearly affected by the myasthenia—for example, the masseters—failed to react abnormally to tapping. So far as I know this condition has not been previously described in myasthenia gravis, and I should be interested to hear opinions as to whether its occurrence here should perhaps be regarded rather as a coincidence than an unusual manifestation of the disease.

## TREATMENT OF NEURITIS BY ELECTROLYSIS.\*

BY

W. BLACK JONES, M.D., B.S.LOND., D.P.H.,  
BULHILL WELLS.

NEURITIS is such a common disease, and its treatment often so unsatisfactory, that no apology is needed for referring to treatment by electrolysis, which gives good promise of relief in cases where the lesion is of the interstitial type, due to inflammation of the nerve sheath.

This method was first published by Dr. Naunton Davies,<sup>1</sup> and its use in sciatica has been described by Dr. E. A. Goulden.<sup>2</sup> The apparatus consists of a pantostat, or similar instrument, with two electrodes, one being a large pad, which is applied to the arm or leg, and a smaller pad or button. An insulated needle, with a platinum point, is fixed in a holder, and is used for the actual treatment. In the absence of an electric supply, a small induction coil can be used for the faradic current, and a battery of about a dozen Leclanché cells for the constant current.

For diagnosis the pads are soaked in warm salt solution, and the larger is applied to some neutral part of the body, such as the wrist; both are connected with the terminals of the induction coil. The current used should be so weak that when the small pad is applied to the normal skin it is hardly felt; when it approaches the site of the inflamed nerve a distinct pain, or series of shocks, is felt. This area is marked with a pencil. Should no tender spot be found it may be concluded that neuritis is not present.

For treatment the skin is swabbed with iodine, and a few drops of local anaesthetic are injected under the epidermis. After a few minutes the platinum needle, having been connected with the negative pole of the constant current, is inserted into the skin and pushed down upon the nerve. The large pad is connected with the positive terminal. If the spot is very tender a current of 1 milliampère or less is applied, but sometimes from 3 to 5 milliampères may be used. The current is allowed to flow for ten minutes; it is then gradually turned off and the needle withdrawn. The wound is protected by collodion.

Only one spot should be treated on the same day, and a day's interval is advisable before the next treatment. The following cases will illustrate the method of treatment.

*Supra-orbital Neuralgia.*

A plasterer, aged 38, had suffered for three years from severe pain in the region supplied by the left supra-orbital nerve. Six spots in all were treated, and he was completely relieved.

In a somewhat similar case, following upon an attack of influenza, a man had suffered from supra-orbital neuralgia for five weeks. He was relieved after two treatments.

*Neuritis and Osteo-arthritis.*

A woman, aged 25, had suffered from pain in the left shoulder for fifteen months; latterly the pain had been so severe that she was unable to sleep. The joint showed signs of osteo-arthritis, there being creaking on movement. Four spots were treated, and complete relief was obtained. The osteo-arthritis was still present, but there was no pain on movement of the joint; this shows that neuritis often occurs around a joint so affected, and is the chief factor in causing pain. The patient went away for the winter, and lived in a damp house; the pain returned, on this occasion in both shoulders. It was found that she had four spots in the left shoulder, in different places from the original areas which had been previously treated, and three in the right shoulder; all were treated and the pain relieved.

*Painful Knees.*

The knee may become similarly affected. A man, aged 54, complained of pain in both knees; one spot was found below the right patella, and on the left side three spots, one on each side of the patella and one below it. He was completely relieved.

*Sciatica.*

The only cases of sciatica that I have had an opportunity of treating are those affecting the small sciatic nerve.

A labourer, aged 49, had suffered from sciatica for two years, and came to me after an acute attack. The gluteal branch of the

small sciatic nerve was treated, and also a cutaneous branch of the popliteal; he was completely relieved.

A woman, aged 59, had suffered from sciatica for several years. After an acute attack two spots on the small sciatic nerve were treated; the pain was relieved.

A man, aged 37, had complained of pain on the left lumbar and gluteal regions; in the part last named the pain had existed for six months. No reaction to the faradic current was obtained on testing the lumbar region, but a tender spot was found over the small sciatic nerve; immediate relief was given by a single treatment.

It is important to note that, in cases of multiple spots, complete relief is not obtained until all the spots have been treated. It is probable that the electrolysis converts the sodium chloride of the tissues into sodium hydrate, and this has a caustic effect on the exudation.

## MELANOTIC SARCOMA OF THE SEPTUM NASI.

BY

PHILIP R. W. DE SANTI, F.R.C.S.,

SENIOR SURGEON TO THE THROAT, NOSE, AND EAR DEPARTMENT,  
WESTMINSTER HOSPITAL.*History of Case.*

A woman, aged 47, went to Golden Square Throat Hospital in October, 1921, for a "lump in the right nostril that kept bleeding"; she could feel it inside the nose with her finger, and it had caused some broadening of the right side of the nose; there was no pain or other discharge. She was seen by Dr. Badgerow, who found a purple tumour on the anterior part of the septum on the right side; portions removed and submitted to microscopic examination proved the growth to be a melanotic sarcoma. In February, 1922, the growth was removed under general anaesthesia with cutting instruments, and the base scraped. The growth was the size of a small walnut, and was attached to the cartilaginous septum on the right side only.

Subsequently (on March 13th) at the Radium Institute she had fifteen hours' radiation (30 mg.) screened with 1 mm. silver in the nostril; again on May 15th and on August 14th. At the end of August she was reported free of growth. Nevertheless, in October, 1922, the patient became aware of another "lump" in the nostril; owing to closure of wards at Golden Square delay took place, and eventually, in March, 1923, she came to me at Westminster Hospital.

I found the right nostril completely blocked by a bluish-black fairly firm growth, bleeding easily on probing; the actual site of origin could not be determined; there was expansion of the ascending nasal process. The left nasal cavity was free; there was no growth in the nasopharynx or the right antrum of Highmore. Microscopically Dr. Braxton Hicks reported portions I removed for examination to be "spindle-celled sarcoma of a type, the cells being large and with large nuclei; in and about the cells undoubted melanin pigment; growth is a melanotic sarcoma (melanoma)." The patient had no ascertainable secondary deposits or enlarged glands and her general condition was good.

On April 4th, 1923, I performed right lateral rhinotomy, which gave good access to the interior of the nose. The growth was clearly growing from the anterior part of the nasal septum, and involved the lateral ethmoidal mass. To remove it thoroughly I had to cut away part of the ascending nasal process of the superior maxilla; I also cut away a large part of the nasal septum and ethmoid, and the tumour was removed *en masse*. Bleeding was not profuse. The orbit was not involved, nor the antrum.

Recurrence was noticed in August, 1923. Radium treatment was given in November and in January, 1924. Considerable reaction followed, and the growth did not appear to have lessened. There was much greater external deformity, and the right maxillary antrum was obviously involved. No enlarged glands or secondary deposits were

\* A paper read before the North Glamorgan and Brecknock Division of the British Medical Association on July 8th, 1924.

detected. Owing to the total closure of Westminster Hospital for repairs, I asked my friend Mr. Harmer to take the patient into St. Bartholomew's Hospital and operate.

Mr. Harmer, who had never seen a similar case, performed the same operation as I had done, but had to cut away a good deal more of the superior maxilla, including most of the anterior wall of the maxillary antrum. He also made free use of diathermy. Immediately after completing the operation the cavity was packed with radium, which was retained for forty-eight hours. Very severe reaction followed the use of the radium. Mr. Harmer reports to me (November 20th, 1924): "The radium burn has not entirely healed yet, but most of the dead bone has separated from the cavity. As far as I can tell there is no evidence of a recurrence of the growth; ultimately I hope for a good result."

#### Remarks.

Melanotic growths, whether classified as sarcomas or carcinomas, are uncommon. I have seen few, and never a case connected with the throat, nose, or ear, and such a case is unknown to most of the rhinologists I know.

The literature on the subject of melanoma of the nose is scanty. Dr. Lack (*Diseases of the Nose*) states: "A few instances of melanotic sarcoma are on record; in one or two the diagnosis seems to have been established without doubt, but in others the pigment was probably the result of old haemorrhages." He refers to a paper by Cozzolino<sup>1</sup> in which a full description is given of an undoubted case of melanoma of the septum nasi. Cozzolino mentioned eight other cases, but in only one of them (Heymann's) does the diagnosis seem to have been beyond doubt; in the others the pigment in all probability was due to old haemorrhages. In Cozzolino's case the growth originated in the right nasal vestibule in a man aged 58; despite removal by snare and cautery it recurred rapidly, and the patient died of sarcoma cachexia and secondary growths in the internal organs. In Heymann's case also the patient lived only a short time, dying with secondary growths.

Melanomas are usually primary growths affecting the skin (pigmented moles, etc.), and containing black pigment—melanin. Spencer, in his Bradshaw Lecture,<sup>2</sup> classifies them as carcinomas. The amount of pigment varies, and usually the secondary growths contain more pigment than the primary. (In my case the primary growth was rich in pigment.) Secondary growths in the glands and internal organs is the rule, and the duration of life short—two to three years. According to Spencer, once the malignant change has started metastasis follows, whether sooner or later; there are instances of great delay in its appearance, such as twenty-two years with four recurrences at intervals, twenty years with recurrence *in situ* after ten years and another recurrence at the end of twenty years.

I was unaware of the presence of pigment in the nasal cavities, but my colleague Mr. Spencer, who saw my case with me at Westminster Hospital, informed me that melanin pigment is regularly present in the olfactory epithelium.

So far my patient has no discoverable secondary glands or metastatic deposits, and the growth is somewhat slow-growing, but it seems to have a marked tendency to local recurrence. No doubt growths in the anterior part of the nasal chamber, shut in as they are by bony walls, tend to remain localized without involvement of the glands for a long while, but in the end, if sarcomatous, they are almost always fatal.

It will be noted that after each operation radium has been employed, and there is no doubt that radium as an adjunct to removal is of great service if the growth is a sarcoma. I have had a long experience of malignant disease affecting the nasal cavities, nasopharynx, and larynx, and I always advocate the use of radium after operations for sarcoma of these parts and for any small recurrences, but as regards carcinoma my experience of the use of radium is exactly the opposite. I have found such growths generally irritated by radium, and often dissemination is hastened.

## THE MENTAL SEQUELAE OF EPIDEMIC ENCEPHALITIS IN CHILDREN.\*

BY

ARTHUR J. HALL, M.D., F.R.C.P.,  
PROFESSOR OF MEDICINE, SHEFFIELD UNIVERSITY.

EPIDEMIC ENCEPHALITIS, although often affecting children, is not predominantly a disease of childhood. About 50 per cent. of the four or five hundred cases in the Sheffield area during 1924 occurred in persons under 16. As great a proportion might occur in epidemic pneumonia or typhoid fever without calling for any special consideration from the children's point of view. Even in those epidemic diseases, such as diphtheria, poliomyelitis, or cerebro-spinal meningitis, in which the central nervous system is more particularly attacked, age alone does not lead to any very noteworthy differences in the results. Similar paralytic, running similar courses and showing similar groupings, are seen in young and old alike. In encephalitis, however, this is not so. Its virus, while attacking any part of the central nervous system, seems to have a predilection for those upper and upper middle nervous centres whose functional development only begins some time after birth, and whose organization and adjustment is not completed until well on in adult life.

Clinical pictures thus appear in children which have hitherto been regarded almost as the prerogatives of adult or even senile years. Children in whom week after week and month after month sleep cannot be induced at bedtime, even by the most patient mother or the most potent medicine, were almost unknown ten years ago. Paralysis agitans under 40 years of age was formerly so rare that Willige, in 1911, could only find records of less than twenty cases in medical literature, and the youngest of these was 18 years of age. Hooliganism, homicide, and suicide in children of tender years are events to which the community is unaccustomed, and for which it is unprepared. Each and all of these are now recognized sequelae of epidemic encephalitis in childhood, and indeed are its special characteristics.

Although it is impossible to arrange the stages of this disease in orderly sequence, yet in whatever order they come there are acute phases and chronic phases. In the former the mental conditions, whether of positive or negative type, differ but little in children from those seen in adults. In both there may be early exaltation and euphoria. One patient, an athletic public school boy, told me that during the first two days of his attack he never felt so fit in his life. In another case a girl was found by her parents dancing in her bedroom in the dark. Incessant and continuous talking all through the night has been often noted; sometimes it is quite unintelligible.

In some cases the child cannot keep still; it rushes about, sings and shouts, tears and destroys its toys or clothes. If delirious, "sums" or other school work form the basis of these patients' delirium; at other times it is something seen at "the pictures." They have visual hallucinations, pick at imaginary objects on the bed, or wave their arms about in an aimless manner. If they were shy and timid before, they are now bold, cheeky, and outspoken. This phase, whether coming earlier or later, does not usually last long; the accompaniments are too severe, and either death occurs or the phase changes to one of lethargy. In other cases there is no marked excitement; the acute phase is, on the contrary, characterized by drowsiness, lethargy, or stupor.

These early mental effects, of positive or negative character, resemble in many points the different effects of alcohol on different persons. One man becomes garrulous, noisy, and truculent before requiring forcible removal, another has been silent and morose for some time before disappearing under the table. The similarity of many acute cases to delirium tremens is a close one and has often been remarked.

\* Contributed to the discussion at the Royal Society of Medicine, January 13th, 1925 (see p. 114.)

*Chronic Phases.*

In the more chronic phases the mental symptoms may be divided for purpose of discussion into four main groups. Some of these are, and some are not, mutually exclusive.

1. *The Idiot Group.*—These cases are practically limited to infants up to 5 years of age. Paterson and Spence<sup>1</sup> reported seven such cases out of seventeen affected at this age. In one of my cases the attack began in December, 1920, at 6 weeks old. The child would lie quite still, apparently asleep, for twenty-four hours at a time, refusing all food. There was slight fever. A week later there was a right hemiplegia. Nocturnal restlessness followed and has remained troublesome during the last four and a half years. She is now a permanent and hopeless idiot. In this group the virus has damaged the upper and upper middle nerve centres in their primitive and undeveloped state, and there is no possibility of effective repair. The question of how to deal with them is no new problem and calls for no new machinery.

2. *The Parkinsonian Group.*—This is more common in children above than below 10 years of age. One of my cases is below that age, and others have been recorded. Paterson and Spence showed a fully developed case in a child of 8. It is not easy to estimate the amount of mental defect in these cases on account of the coexisting motor disabilities. There appears to be some loss in many of them; but on the other hand one is often surprised to find their minds so clear, in spite of the bodily inertia. Much depends on the extent of the Parkinsonism itself, and perhaps more on whether there is, as so often happens in these cases, some wider involvement of the nervous system as well, such as occurs in the two following groups.

3. *The Apache Group.*—The prototype of this group has for long existed in our larger cities, but he is usually rather older. Moreover, he has developed gradually. It is the curious property of the virus of encephalitis that it can suddenly unmask this type in a child who has previously shown no trace of such tendency. In fact, the number of cases of this and the next group who have been described as being hitherto unusually clever at their books, or particularly docile, is quite surprising. In this type the child becomes completely changed in character. He is aggressive, cheeky, and untruthful. He quarrels and fights with his fellows, wanders abroad, is dirty in his habits, shows sexual tendencies, and may even be homicidal or suicidal. Only rarely have these last features been recorded, but one such case occurred in the North of England in a boy of 15. He nearly strangled a girl who had laughed at him, and afterwards hanged himself. While this group consists chiefly of boys, girls may be similarly affected, the kind of symptoms differing with the sex. I have seen one typical case in a girl of 17 necessitating certification, and another younger girl under my care is almost as bad. How best to deal with these cases presents the greatest difficulty. Before considering their mental condition it will be well to take the next group.

4. *The "Difficult Child" Group.*—It is not easy to draw a line between this and the preceding group; indeed, the difference seems to be one of degree rather than kind. Among the cases which I have seen by far the greater number can as yet be classed under this heading. They, too, are excitable, irritable, and quarrelsome. Most of them have nocturnal restlessness and insomnia—but can sleep soundly and well when it is near "getting-up" time. If they did not they would obviously become physical wrecks. On the contrary, they are as a rule, in their waking hours, surprisingly alert and active. They are difficult to control, the difficulty varying inversely with the skill and efficiency of those around them and with the nature of their environment. Mental efforts soon tire them. That they are mentally inferior to what they were before and to what they ought to be is generally agreed, and this defect is increased by their long illness. Like adult psychasthenics, they cannot concentrate; they have lost the habit of sleeping at night, and their emotions are dulled or even abolished. One little boy of 6, a bright, lively little fellow, tells his parents that they cannot make him cry now, and it is quite true. This loss of emotional affectivity in childhood deprives the parent of the chief means of guidance and control. It

is as though one were astride a colt being broken to harness, and the reins suddenly gave way. The whip is now worse than useless, and it requires good horsemanship and suitable country to regain control and escape trouble. That these children can be controlled is shown in many ways. Most of them improve considerably while in hospital with its orderly régime and moral influences. They sleep better and improve generally. Some of them continue this improvement after going home, others relapse in bad environments. They improve also when sent away to the seaside or country, where they are out of doors all day. Conversely, after improving for a time, they are easily made worse by any excitement, even a visit to "the pictures."

There is a considerable danger of exaggerating the number of cases belonging to the apache group. Such cases by their very nature attract so much attention that there is a tendency to magnify their numbers. Personally I have only seen very few that can properly be classed as such. Others who really belong to Group 4 are made worse than they need be by the folly of those in control of them. The child's threats and doings are talked of so much in its presence that it is encouraged to do even greater things.

*Treatment.*

The problems of treatment are many and difficult. Two points stand out prominently: (1) How to protect the community against the apache, and at the same time, if possible, reform him; (2) how to prevent the difficult child from developing into an apache or a wastrel. While institutional treatment may be necessary for the former, in the public interest, yet the collecting together of this type of child and the absence of individual control has many drawbacks for him personally: he needs very much the haven of normal persons around him.

In the case of the difficult child, institutional treatment must, if tried at all, be something very different from that which is usually provided under this name. The requisites seem to be: fresh air (seaside or country), small numbers, close individual supervision, plenty of rest interspersed with regulated physical exercise of a congenial kind, carefully graded mental work under an experienced teacher, plenty of good food. It is an expensive and difficult ideal to carry out, but the numbers in any locality would not be large, and it seems as great a thing to save a damaged mind as to save a diseased limb.

### TREATMENT OF SPRUE WITH CALCIUM AND PARATHYROID EXTRACT.

I HAVE read with interest Dr. H. H. Scott's account of the successful treatment of sprue by calcium lactate and parathyroid extract in the *JOURNAL* of August 23rd, 1924. I have had some experience of it, and report the following remarkable case, in which symptoms like those of sprue were manifest, together with paresis, loss of tone, or trophic changes in the terminal nerves of the intestines, liver, stomach, ear, and skeletal muscles. The trophic, or, more correctly, the dystrophic, changes provide the pathological basis of the signs and symptoms of the sprue-like condition in this case, and I advance the tentative hypothesis that sprue is not due to any specific organism, but mainly to this exhaustion of the nerve centres or of endings in the viscera in general, particularly of the intestines. Though there are no definite pathognomonic signs in the intestines affected the condition arises solely from the lack of certain principles, supplied by the calcium and parathyroid treatment, and concerned in the causing and curing of sprue. The lack of these principles may affect the nerve terminals in the intestines, as when large, bulky, undigested, foul, fermenting stools occur in sprue, or may involve the nerve centres or the nerves themselves supplying the various organs—such as the auditory nerve when deafness and

timitus occur, as in the case here reported. Symptoms of mental exhilaration or depression occur when the brain is similarly affected. In fact sprue, and sprue-like diseases, may be regarded as deficiency diseases, caused by lack of some vital principle other than the vitamins. It may be the lack of the metal calcium which causes the neurosis.

The patient, a male, aged about 48, European, had lived in the East for more than twenty years. He complained of sore tongue and indigestion, and later of frothy, fermenting white stools, with considerable loss of weight. He had had malaria and gonorrhoea previously. From being a very sociable and entertaining man, he became very peevish and depressed in mind after the onset of symptoms, which, however, ceased when the patient was put under rigorous diet restriction and a nitro-hydrochloric mixture. Rich feeding brought on a relapse, and he now complained of deafness, a feeling of weight, and pain in his right ear, and of hearing noises. The right ear was found to harbour a fungous growth, and when it was cleared out, a discharge and tinnitus remained. The latter was very persistent, although the discharge was cured by treatment. The liver being markedly enlarged he was given emetine, which seemed to do him a little good. Symptoms of sprue again set in, however, but the discovery of the calcium and parathyroid therapy gave him new hope, and he started treatment once more, to find himself, in his own words, "cured." The cure was not complete, wasting being very marked, and there being also mental depression. He got tired, and ceased treatment, and tried a change of surroundings; this did him much good for a time, and he returned able to eat well. He is still under the treatment and is better, but the ear noises persist; he has lost a considerable amount of weight, and has to diet himself occasionally.

#### PERFORATION OF CHRONIC DUODENAL ULCER IN A BOY.

It will, I feel sure, be of interest to record this case of perforation of a chronic duodenal ulcer in a child of 14 years, not only on account of the rarity of this occurrence in a child of these tender years, but also in support of Dr. A. F. Hurst's theory of congenital predisposition to duodenal ulcer, set out in his address on the hyper-thenic gastric diathesis. The early age of this patient—an age at which the abuse of diet and general hygiene, one would think, had not had time to produce such disease—the nature of the ulcer found, and the general condition of the stomach at the time of operation, all help to convince me that the predisposition was so great that it did not require any powerful secondary exciting cause to produce the result.

On November 10th, 1924, I was called to see D., aged 14, who had been taken violently ill the previous evening with severe abdominal pain; I saw him at about 2.30 p.m., and learnt that after an unusually good tea the previous day he had been playing until 7.30 p.m., when he suddenly collapsed with pain; he became white, and screamed. He was put to bed and spent a restless night, vomiting and distressed. Finding him no better the following morning, his mother sent for me about mid-day. When first I saw him he looked very fit and did not complain much; his temperature was 102° and his pulse 140; he was generally tender all over the abdomen, with perhaps a particular selection for the region of the right iliac fossa. The tongue was muddy and offensive. I determined he had a perforated appendix with general peritonitis, and at once ordered his removal to hospital.

I operated at about 4 o'clock, and opened the abdomen through a right lateral rectus incision, as for an appendix. There was a quantity of free fluid, and the parietal and visceral peritoneum were both intensely inflamed. The appendix was found to be normal and was removed. The wound was then extended upwards, so as to expose the stomach. On the anterior wall of the first part of the duodenum, and attempting to adhere to the under surface of the liver, was the perforated base of an ulcer. The ulcer was about the size of a shilling, hard and crateriform, and had at its base a perforation about the size of a pea. This perforation was closed with a fold of the gastro-hepatic omentum, and a posterior gastro-enterostomy performed. The muscular wall of the stomach and the gastric mucous membrane were both found to be much hypertrophied when one came to cut into them, and the latter was intensely congested. Drainage was effected through an opening in the lower portion of the abdominal wall and the wound closed. The patient made an uninterrupted recovery and was home at the end of sixteen days.

The previous history of this case is interesting in view of these later events. The boy had pneumonia in 1918, and began to complain of abdominal pain some twelve months ago. He always had an unusual appetite and was always craving for food, even between meals. His teeth were quite normal, and there is no evidence of sepsis either in his throat or nose. He has a scar on his right cheek, the result of a birth injury which tore open his cheek practi-

cally from the angle of the mouth to the ear. It is of interest to record that some nine months ago I removed a perforated appendix from his mother.

#### ENCYSTED PSOAS ABSCESS: OPERATION: RECOVERY.

A WOMAN, aged 40, had pleurisy in 1899, and "very advanced" lateral curvature of the lumbar spine in 1902. She was treated in bed for six months, and recovered.

In March, 1924, she complained that her right thigh was stiff, and that she could not cross the leg over the other. She presented small lumbar kyphosis and a large boggy fluctuating swelling in the region of the right hip and the upper half of the thigh. There was resistance and dullness in the right flank, but no fluctuation between abdomen and thigh was detected.

On April 23rd 50 ounces of fluid were aspirated, thick with cholesterol crystals and resembling an emulsion of gold dust. By May 25th the fluid had reaccumulated.

On June 4th the sac was exposed beneath the tensor fasciae femoris. Its wall was thick and white, and the cavity burrowed deeply beneath the glutei and the muscles of the upper thigh. The lower part of the sac wall, about 8 in. square, was dissected out and removed. The cavity was left open to drain into the intermuscular planes.

In December, 1924, there had been no recurrence, and the patient was not conscious of discomfort.

The case illustrates the favourable termination of lumbar curvatures with curvatures and psosas abscess. The patient's carriage and figure are now well above the average.

#### AIR EMBOLISM FOLLOWING URETHROSCOPY.

I report this case in order to emphasize a little known source of danger in using the aero-urethroscope.

A man, aged 30, was sent to the Chester venereal clinic with a history of a recent slight haemorrhage from the urethra. He denied having exposed himself to infection, and there was no obvious discharge, although gonococci were subsequently found. The urethroscope tube was passed and I examined him in order to try and locate the cause of the bleeding. In a few seconds after starting inflation we noticed a general tetanic spasm; he then became profoundly collapsed, quite unconscious, and pulseless. His breathing was shallow and irregular. On auscultation of the heart numerous musical sounds were heard, which at once suggested the presence of air. He remained in this state for nearly an hour, and then only slowly recovered. He was admitted as an in-patient, when it was found that his vision had almost completely disappeared. Next morning he appeared to be quite normal and the only physical sign noted was a slight systolic bruit.

I have assumed that the cause of the collapse was an air embolism due to a direct communication between the source of the previous bleeding and the cavernous sinuses.

### Reports of Societies.

#### DRUNKENNESS: ITS SIGNS AND MEDICO-LEGAL ASPECTS.

At a meeting of the Society for the Study of Intebriety on January 13th, Sir WILLIAM WILCOX presiding, Sir JAMES PURVES-STEWART gave an address on the subject of drunkenness, and particularly on the tests to be employed in assessing intoxication.

Sir James Purves-Stewart said that in the *Oxford Dictionary* a drunk man was defined as one who was overcome with liquor. This was not quite synonymous with alcoholic intoxication, because a person might have taken a mildly toxic dose of alcohol insufficient to overcome him or make him drunk. At what stage of alcoholic intoxication was a man to be regarded as drunk? According to a legal dictionary, no statutory definition of drunkenness existed, and a man might be held drunk in connexion with one offence when he would not be held drunk in connexion with another. The degree of intoxication which would make an engine-driver drunk if he were driving an express train would not legally make him drunk if he were walking

along a country lane. Medical men had to be more precise, and he would submit the following definition:

A drunk person is one who has taken alcohol in sufficient quantity to poison his central nervous system, producing in his ordinary processes of reaction to his surroundings a temporary disorder which causes him to be a nuisance or danger to himself or others.

In the eyes of the law a person was liable to punishment, not for being merely drunk, but for some combined offence, such as being drunk and incapable. Alcohol intoxication occurred when the quantity of alcohol absorbed became enough to poison the central nervous system and disturb its normal reactions. The total amount necessary to produce nervous symptoms varied widely in different persons. The seasoned toper might consume large and increasing quantities for many years and never show any signs of drunkenness, while the habitual teetotaler would become drunk if he tried to keep up with him for an hour. Alcohol swallowed before or between meals was more rapidly absorbed than when taken with or immediately after food. Fatigue and excitement might predispose to rapid alcoholic intoxication. A sudden fall in atmospheric temperature might precipitate drunkenness. The most rapid method of alcoholic intoxication that he knew was intravascular injection.

One of the early effects of moderate doses was to dull the critical and inhibitory centres in the cerebral cortex. Everyone who organized a charity dinner knew how alcohol set free the latent generous impulses of the diners; therefore the subscription list was never sent round until near the end of the banquet. The lower muscular centres might also become imperfectly controlled. Cerebellar inco-ordination might be brought to light by a sudden change of posture. Many guests only realized that they had dined not wisely but too well when the time came for them to rise from the table. Double vision was not uncommon. Hughlings Jackson used to tell the story of a Scotsman who said to a fellow Scot: "When ye gang oot o' the door, Tam, ye'll see twa cabs. Jist get intae the first yin, for the second yin's no there." Indistinctness of articulation was another frequent sign. Alcoholic vomiting might tend temporarily to aggravate the nervous symptoms. The smell of alcohol was conclusive evidence that alcohol had recently been swallowed, but of nothing more, for it might be produced by a single glass of alcoholic refreshment. City men took cloves and other aromatics after their mid-day sherry to mask the smell. Alcoholic hiccup occurred only at an early or moderately advanced stage of alcoholic poisoning. A deeper stage was alcoholic stupor, but even here it was well to be cautious. An alcoholic aroma in a comatose patient, though suggestive, was not conclusive evidence of alcoholic poisoning. An intercurrent attack of apoplexy might have supervened, or the man might have fallen and sustained a head injury. Unilateral signs, such as localized paralysis, pointed to a unilateral intracranial lesion. The urine should be examined to exclude diabetic and uraemic coma, while various other poisons such as veronal could be recognized by appropriate tests of the gastric contents, urine, or cerebro-spinal fluid. Typical alcoholic stupor was a less profound degree of unconsciousness than that of opium or veronal poisoning. The diagnosis of drunkenness was often so easy that it was arrived at by non-medical observers, in most cases of police, and was confirmed, or otherwise, by the police surgeon. In nine cases out of ten the policeman's diagnosis was correct. There was a good deal of loose thinking on the subject of tests for drunkenness. With the possible exception of a positive reaction for alcohol in the cerebro-spinal fluid, there was no single clinical sign which was pathognomonic of alcoholic poisoning of the central nervous system, because drunkenness was not a single entity, like a broken bone or a consolidated lung, but a way in which certain nervous tissues reacted, as evidenced by a whole series of transient phenomena following the initial poisoning. He then went on to consider in detail some of the commoner clinical phenomena observed by medical men as tests in the recognition of drunkenness at a given moment. In his opinion disorders of articulation, to be of value in establishing the diagnosis of alcoholic intoxication, should be present in the pronunciation of words which the particular

individual was likely to use in his ordinary conversation. It was all very well to try an elocutionist or a schoolmaster with tongue-twisters, such as "terminological inexactitude," but to expect perfection in such phrases on the part of the chauffeur, especially at a time of emotional shock following arrest, was unfair. Disorder of the reflexes was of no practical value in the recognition of alcoholic poisoning. The exaggeration of knee-jerks and other deep reflexes was sometimes mentioned by medical officers as indicating acute alcoholic poisoning, but the degree of briskness of these reflexes varied so widely in normal individuals that their exaggeration could not be regarded as of diagnostic significance.

His general conclusion was that in slighter cases of supposed drunkenness two distinct and successive facts must be proved to have occurred in order to establish a diagnosis. First, it must be shown that the person had recently taken alcohol; secondly, the reactions of his central nervous system to his surroundings must be shown to be temporarily disordered to such a degree as to be injurious to himself or to other people. If a person already suffered from disease of the central nervous system, thereby preventing the corresponding cerebral, cerebellar, pontobulbar, or other symptoms, and happened to come under observation after taking alcohol in the most moderate amount, he might easily be the victim of an injustice. But in such a patient the phenomena would not be temporary; they would be present both before and after the alleged poisoning. There was also a class of persons in whom transient excitement, due to such a circumstance as being arrested, might simulate alcoholic poisoning of the central nervous system. When the decision was doubtful, it was the duty of the medical officer, resisting the human tendency to corroborate without careful consideration the snapshot diagnosis of the police-constable, to give the patient the benefit of the doubt. Matters were different, however, in cases where, superadded to the alcoholic breath and emotional excitement, there was incoherence of thought and speech, together with signs of temporary cerebellar and pontobulbar disorder. The important point, after all, was not whether the person could perform various elocutionary or acrobatic feats, but whether he was in a fit condition to pursue efficiently his ordinary daily avocation.

In the deepest stage of alcoholic poisoning, where stupor had supervened, the history and surroundings of the case, together with the appearance of the patient, were usually characteristic, but other varieties of coma must be excluded, not only those arising from outside poisons, such as opium or veronal, but also from autogenous toxins, as in diabetic and uraemic coma. The possibility of gross vascular lesions, such as cerebral or pontine haemorrhage, and traumatic lesions, as in head injuries. There was no short cut to accurate diagnosis. The only safe guide was a careful and systematic clinical examination. The main difference between a superior medical opinion and one which was less valuable was, not that the one man necessarily knew much more than the other, but that he was wise enough to make a more careful and more accurate examination of his cases.

#### Discussion.

The ensuing discussion was almost entirely confined to a few remarks from two or three divisional police surgeons. Dr. M. I. FINEANE felt strongly that medical men must not overlook the enormous responsibility which was theirs in view of the increasing and very serious dangers to the community which drunken people brought about in these days of mechanical transport. In his experience, in 99 per cent. of the cases which came before the divisional surgeon the police had been right. He gave particulars of the examination which he conducted, and which lasted half an hour or longer. Dr. MATHAN also described his procedure, and said that after eliciting what the person had had to eat and to drink, and his account of the accident, he devoted usually not less than three-quarters of an hour to physical examination. Dr. BLACKETT referred to the usefulness of the time test. If a person under the influence of alcohol were asked to tell the time without looking at the clock he was generally an hour or two out. Another member of the audience referred to Dr. Eyslop's contention that the

process of becoming drunk began as soon as a man's judgment was affected. Another member referred to the strong position taken by the automobile authorities on this point. One of the leading motor journals had said that motorists must realize that even the smallest quantity of alcohol had deleterious effects on their driving.

Sir WILLIAM WILLECOX, in closing the discussion, referred to the great difficulty arising in the case of persons who might be subject to organic defects of various kinds. Some little time ago he gave evidence in a case of alleged drunkenness, in which the examination showed some signs of nervous instability. Within three months that person developed grave organic nerve disease. No doubt the phenomena exhibited at the time of the accusation were due to the oncoming symptoms. He had never met with a case in this country of optic atrophy occurring as the result of the taking of alcohol, but he had seen one such case in the United States. There was no doubt that impure wood spirit did give rise to retrolbulbar neuritis which might be followed by optic atrophy, and in these cases generally it was not only the optic nerve that was damaged, but there was considerable other damage as well. In the case he had seen the patient developed grave mental disorder, due no doubt to the effects of this impure alcohol, and the case terminated fatally. The lecturer had referred to the extensor plantar reflex; this Sir William Willecox had not seen in cases of alcoholic stupor, but one knew that it did occur with many of the narcotic poisons—veronal, salvarsan, sulphonal all gave it—and an extensor plantar reflex might be shown in cases of coma from bacterial poisoning. In general he could only say that the diagnosis of drunkenness was in many cases very easy, but in some cases in which the intoxication was slight, and in which the person might be subject to some functional or organic nervous disorder, the diagnosis was extremely difficult, and he was sure that Sir James Purves-Stewart's address would prove to be of great assistance.

### THE MENTAL SEQUELAE OF ENCEPHALITIS LETHARGICA.

Four Sections of the Royal Society of Medicine (Psychiatry, Neurology, Disease in Children, and Epidemiology) combined in a discussion on January 13th on "The mental sequelae of encephalitis lethargica." Dr. R. H. COLE was in the chair.

Professor M. BRAMWELL (Edinburgh), in opening, said that recent experience of epidemic encephalitis had served to demonstrate that the clinical picture and the ultimate outlook were both much more varied than was at one time believed. It was now known that in some cases the onset was insidious and the course slowly progressive, and it was generally recognized that months, or even years, after the patient appeared to have made a more or less complete recovery remissions might occur. It was impossible even to express a dogmatic opinion as to when the patient was to be regarded as out of danger, and as to whether or to what extent the existing manifestations of the disease cleared up. Were the mental symptoms themselves sufficiently characteristic and distinctive to permit of a diagnosis apart from the help that might be afforded by the history and the presence of physical manifestations? Personally he believed that this was rarely if ever possible. He went on to draw attention to the mental sequelae which had specially impressed him. In the case of adult patients the complaint was often made by them—if they complained of anything at all—was (in his own words, of course, not in theirs) slow cerebration, mental fatigue, and defective application. It was almost unnecessary to remind his audience that in those cases in which the Parkinsonian syndrome was present the expressionless face so well recognized might give a misleading impression of the patient's mental capacity. Another feature was that the patient who had had a more or less acute attack of epidemic encephalitis could seldom recall any of the events pertaining to the earlier stages of his illness. These people, however, seemed to regard their condition, mental and otherwise, very complacently. Pronounced mental depression was very uncommon. He had never met a case of suicide, although two or three patients of a nervous temperament had volun-

teered the remark that they felt as if they might do something desperate. A true psychosis calling for certification was, to judge from his experience, a very exceptional sequel to epidemic encephalitis. Disorientation and more or less mental confusion were often observed about the time of onset of an acute case, and he had met with two or three cases in which the patient was maniacal. These phenomena, however, were to be associated with the acute stage of the disease, and not as sequelae in the true sense of the word. On the other hand, he had been impressed with the number of cases in which the patient found himself unable to cope with his duties on returning to work, and the patient's recognition of his incapacity had led to sleeplessness and other secondary psychological conditions. In children the great majority of the cases he had met with had conformed closely to the adult type, though there were differences. He had met with a number of cases in which parents had remarked on the altered disposition of the child and had complained of his irritability and inchoiveness. In only one of his cases was moral deterioration present to a pronounced degree at the time the patient came under observation. These moral defects did not appear to be met with in adults. Another thing met with in children, but not often in adults, was the disturbance of the sleep rhythm. The speaker dealt with points to be noticed in diagnosis, and referred to the great importance of the Parkinsonian syndrome. Some slight immobility of the face, an unnatural pose of the arm or hand, or an apparent stiffness about the trunk had suggested the appropriate line of inquiry; otherwise one might have failed to recognize the condition. A great variety of tremors and anomalous movements also were met with, and all such movements should nowadays bring to one's mind the possibility of epidemic encephalitis.

Professor ARTHUR J. HALL's remarks are printed in full this week at page 110.

Dr. F. G. SHRUBSALL brought forward some figures obtained in the London school medical service. Reports had been obtained in the latter part of 1924 relating to the condition of 119 children who, earlier in that year, had been reported as suffering from encephalitis. Of this number 26 had apparently completely recovered, and 93 partially recovered. The predominant symptoms at present were: impaired sleep, 40; impaired intelligence, 26; paresis, 6; twitchings, tremors, or "fits," 12; ocular symptoms, 10; conduct changes, 44. The proportion of cases which seemed to have recovered completely was low, but it was probable that the milder cases did not come under notice. The most characteristic of the mental changes was irritability, the rapid onset of fatigue, lack of continuity of attention, such as was noted in those recovering from influenza, but in the case of encephalitis the condition persisted for a prolonged period. The common story from the schools was that the subject's work had fallen off badly, his attention wandered, and he was sleepy. The changes of conduct noted were of a varied character, but seemed to take their origin in the state of irritability, lack of inhibition, and consequent impulsiveness which immediately followed the acute phase of the illness and became fixed either by habit formation or by a secondary development of psychoneurosis dependent on the particular features of the individual environment. Dr. Shruballs gave a remarkable account of the conduct changes in some individual instances. One of these was a theft mania, which took the form of persistent stealing of bicycles, the culprit endeavouring to sell the machine after having had his "joy ride."

Dr. A. S. McNALLY, in a joint contribution from Dr. ALLAN PARSONS and himself, dealt with the epidemiology. He said that encephalitis lethargica was a disease which was claiming an increasing toll of victims. The notifications for 1924 largely exceeded the figures for each preceding year. From 1919 to 1923 the inclusive case mortality had averaged about 50 per cent. on the basis of the notified cases, but during the recent outbreak there had been indications that the severity of the disease had declined. It was sufficiently established that the disease brought in its train sequelae of both neurological and medico-legal importance. The manifestations of the after-effects of encephalitis lethargica might be grouped into (a) those appearing in the course of the original acute

malady and persisting after partial or complete disappearance of all other symptoms, and (b) those which ensued after the original acute malady had apparently terminated or, in some cases, had passed unrecognized. It was as yet unknown whether the late manifestations were true after-effects or were indicative of the persistence of the original infection, an interval of latency having occurred. Investigations were now being made by the Ministry of Health on this question. In a number of instances reported to the mental condition had been such that it was necessary for the patient to be certified. The great frequency of the Parkinsonian syndrome was a marked feature in Continental literature; it was difficult to say whether the fact that the acute illness passed unrecognized and unmanifested could not be ignored, however, the late disease were more pathetic than juvenile cases of pargia. agitants, familiar to the neurologist since 1919. The treatment and provision of institutions for patients presenting Cases of mental disorder following on encephalitis lethargica in the adult appeared, on the whole, to be more recoverable than similar conditions in children. At the same time, it was his opinion that many juvenile cases, if recognized early and suitably and sympathetically treated, would do well. Between these cases and the severe mental disorders with hopeless prognosis were a number of cases of mental derangement in which special treatment would be well worth trying with a view to recovery. Facilities were needed also for medical observation and study of these conditions. The question of making provision for the special care and treatment of the after-effects, especially the mental, was under the consideration of the Ministry of Health and other Government departments at the present time.

Dr. P. C. P. CLOARE said that the mental symptoms which arose in toxic infections states were of a fairly uniform nature, chiefly impairment of apprehension of environment, of the power of retaining mental impressions, and of memory and its activation, and variability in mental capacity and the level of attention. These disturbances resulted in the well known clouding of consciousness, often amounting to delirium, with hallucinations, illusions, and disorientation. It was important to realize that the mental symptoms of acute lethargic encephalitis belonged essentially to this toxic infectious group. But in addition there was one most important complicating factor, one which gave the disease its distinctive character, and was closely bound up with the pathogenesis of all its mental manifestations; this was lethargy. Though the other acute mental symptoms appeared to be due to a toxic affection of the brain, and hence were more marked at night, when toxic effects were commonly most apparent, it was difficult to escape the view that lethargy arose from quite another cause. The lethargy appeared to be due to the localization of the disease process predominantly in and about the mid-brain. Sometimes lethargy preponderated, and the toxic symptoms were slight; in this case the state of prolonged sleep was found to be common in the early days of the acute illness; at other times the toxic symptoms were more severe, and there was an active delirious state at night which might continue in a milder form during the day. The view that the lethargy was not a result of the toxæmia was supported by the fact that it was quite easy, as a rule, to wake the patient up, when he was frequently as clear as if awakened from normal sleep—a very unlikely possibility if the drowsiness were really a toxic manifestation. In the coexistence of lethargy, a phenomenon perhaps dependent upon inflammatory reaction in the mid-brain, and the toxic infections mental symptoms of acute encephalitis lethargica. The speaker went on to consider closely the mental symptoms of cerebral damage, and to argue that psychoses of the constitutional type probably did not occur, except as accidents, in relation to encephalitis lethargica.

The further discussion was adjourned to a later meeting, provisionally fixed for January 27th.

## CANCER OF THE OESOPHAGUS.

A JOINT meeting of the Sections of Surgery and Laryngology of the Royal Society of Medicine was held on January 7th, with Mr. H. J. PATERSON, President of the Section of Surgery, in the chair.

Mr. H. S. SOUTAR read a paper on carcinoma of the oesophagus, which during the decade 1910-20 was responsible for 16,000 deaths, 12,000 of the deaths being in males, and constituting 7 per cent. of the deaths of males from cancer. The preponderance of males affected would have been even higher had not the post-cricoid cancer been so common amongst women. It was for this reason that statistics collected from different sources might show very different proportions—the number of female cases being much higher in laryngological practice. Three common sites for cancer of the oesophagus were well recognized—at the commencement, in the middle where it was crossed by the left bronchus, and at the lower end. In men the cancer occurred more often in the lower sites, but in women the post-cricoid form was three times more common than either of the others. Most cancers of the oesophagus were squamous-celled, exhibiting large numbers of cell nests and marked keratinization, but occasionally medullary forms occurred, these usually spreading from the stomach. The growth was generally circular and single, though multiple strictures might occur from lymphatic permeation. At *post-mortem* examinations the extent of the growth was often astonishing, the greater part of the gullet being replaced by a tube composed of cancer cells, which alone shut off the structures of the mediastinum. Death usually occurred from perforation into a bronchus with resulting septic pneumonia. The average duration of life after the first symptoms was about twelve months, and as a rule the cases were inoperable, from the point of view of radical cure, when symptoms began. The symptoms of the disease were—(1) dysphagia in spite of a good appetite; (2) the regurgitation of small quantities of food, usually early in the morning, after which the patient might be free from this for the rest of the day—thus differing from the copious and repeated regurgitations of cardiospasm; (3) hoarseness; (4) dyspnoea from mechanical pressure on the trachea or bronchus; (5) marked and rapid wasting, which a remarkable recovery was made after intubation; (6) cachexia was a late symptom. Three methods of local examination were available—by bougies, by the x rays with a bismuth meal, and by the use of the oesophagoscope. While the danger of bougies had been exaggerated, the speaker preferred only to use them in conjunction with the oesophagoscope. The x rays had proved most useful, not only in the diagnosis of the tumours, but also in showing the extent and nature of the stricture. As regards treatment, no radical operation was as yet feasible except perhaps in a very few cases of cervical growths, so that palliation was all that was aimed at. Opinion was divided as to the use of x rays and radium, but in his hands these had been disappointing. The stricture of the oesophagus might be dilated by bougies, but the effect of this lasted only a few weeks, whereas intubation gave more permanent relief. He now used a modification of Symonds's tube, consisting of coiled German silver wire, elliptical in section and having a slightly spiral form. These were introduced along a flexible bougie after dilatation of the stricture as far as was safe, the whole operation being performed under direct vision through the oesophagoscope. The patient was quite unconscious of the presence of the tube and was able to wear it indefinitely, so that he was given complete relief from the stricture. This had the advantage over gastrostomy that the patient was able to eat finely divided food and to swallow his saliva.

Dr. G. E. VILVANDRÉ showed a number of x-ray photographs of carcinoma of the oesophagus as well as of other conditions with which it might be confused, notably cardiospasm and pouches, and pointed out the differences in the appearances in these conditions. While the x rays could usually establish the diagnosis, a few early cases might be missed unless the oesophagoscope was also used.

Sir STCLAIR THOMSON pointed out that dysphagia was often a late symptom, and urged that when elderly people began to lose flesh without any other obvious cause the oesophagus should be explored by the oesophagoscope, which would reveal a growth before x rays could do so. Many cases of oesophageal cancer died of chest symptoms without having had any dysphagia at all. He inquired what was the general feeling about gastrostomy—was it usually performed too late or should it never be performed at all?

Sir CHARTERS SYMONDS thought it remarkable that Mr. Souttar's wire tubes did not in time work downwards through the growth—possibly this accident was prevented by the penetration of the growth through the interstices of the wire. He had never seen an accident from the use of bougies, but care must be taken not to force them down when the patient was regurgitating. As regards the diagnosis, dysphagia was not always present, and he had seen a case in which the first symptom, contrary to general experience, was distasto for food. He considered that gastrostomy was never necessary, since it was possible to intubate any part of the oesophagus, even the lower end.

Dr. WILLIAM HILL considered that the statistics of cancer of the oesophagus had been falsified by the inclusion of many cancers of the pharynx. The level of crossing of the left bronchus was not, in his opinion, a special site for cancer, but the whole of the middle third (the part generally most affected by swallowing escharotic fluids) was liable to be affected. Dysphagia was a late symptom and the x rays were not to be relied upon for early diagnosis, which could only be made with certainty by oesophagoscopy. He held a brief for radium treatment, from which he had had some very successful results, but added that its successful application required a special technique. Recently he had tried diathermy in a few cases. He regarded Symonds's tubes as invaluable.

Sir JAMES DUNDAS-GRANT traced the progress of the treatment of carcinoma of the oesophagus. He suggested that rubber tubes might have a "dilator effect." Several cases of post-cricoid cancer in young women had been due to the loss of teeth and resulting bad mastication. Gastrostomy was a dangerous operation if performed late, but where successful gave great relief; some of his patients had been able to return to work after this operation.

Dr. G. F. STEDING said he used a Symonds tube of a material with which bismuth was incorporated. He considered that little advantage was to be gained by passing bougies through an oesophagoscope, since only the top of the stricture could be seen, whereas the x rays would reveal the whole course of a stricture. A bougie properly handled was free from danger and followed the windings of the stricture. Many of his cases had already had a gastrostomy performed; in such cases he intubated the stricture and allowed the gastrostomy to close, since patients invariably preferred the oesophageal tube.

#### Fat Necrosis of the Breast.

Mr. GEOFFREY KEYNES read a short communication upon a case of fat necrosis of the breast. The patient, a spinster aged 50, presented a hard tender nodule in the upper and outer quadrant of the breast; this was attached to the overlying skin, which was slightly dimpled. No enlarged glands were palpable. A clinical diagnosis of carcinoma was made without hesitation, not only by the speaker, but also by three other surgeons. At the operation the lump was cut into, and small white areas, surrounded by a zone of infiltration, were revealed. A frozen section showed large polyhedral cells which, though larger than the usual carcinoma cells, were regarded as cancerous; a radical amputation of the breast was therefore performed. Paraffin sections cut subsequently to removal, microphotographs of areolar tissue with infiltration of necrosis in fatty leucocytes, and, in places, numbers of large polyhedral cells, now identified by Sir F. Andrews as embryonic fat cells. There were also scattered through the section some large multinucleated giant cells, the nuclei of which were centrally placed. Though there was no blood pigment in the sections, and no history of injury, there could be little doubt that the origin of the fat necrosis was traumatic.

Five similar cases reported in America were all traumatic in origin—three from saline infusion and two from blows. Mr. Keynes considered that the chalky whiteness of the necrosed areas, resembling the "fat necrosis" of acute pancreatitis, combined with a history of trauma, should suggest the true diagnosis to a surgeon who was on his guard against this very rare lesion. In reply to a question, Mr. Keynes said that the breast tissue itself was normal, and that the tumour lay in the subcutaneous fat superficial to the true glandular tissue.

#### RESEMBLANCES BETWEEN LEPROSY AND TUBERCULOSIS.

At a meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on January 8th, Dr. L. S. DUNGEON presiding, Sir LEONARD ROGERS delivered a lecture on points of resemblance in the epidemiology and treatment of leprosy and tuberculosis.

Sir Leonard Rogers, who illustrated his remarks by reference to maps of India showing the distribution of these two diseases and the geography and climatology, pointed out that when leprosy reached an area where climatic conditions were favourable to its spread, and where it had not occurred before, it tended to take an epidemic form, and the same was true of tuberculosis when it affected tribes and races hitherto free, as instanced in the Sandwich Islands and islands off the South American coast. It had to be remembered that in the greater part of Europe and the United States the great majority of the population of over 15 years of age had been "tuberculinized"—that is to say, infected with the tuberculous organism, although mostly without symptoms—and this fact obscured to some extent the relationship of the disease to climate and other factors. Both leprosy and tuberculosis were essentially house infections. Formerly tuberculosis was looked upon as hereditary, and leprosy also, as late as 1860-70, was considered by all European authorities to be essentially hereditary; but it was now known that this was absolutely untrue. The theory of hereditary predisposition had been suggested in connexion with both diseases, but the general opinion now was that in both this was a doubtful factor. Young people were much more susceptible than older people to both infections, and for this reason the conjugal relationship played only a very minor part as a source of infection. He believed the incubation period in leprosy to be shorter than was usually supposed—in the majority of cases not more than two or three years, rarely over five years—and some recent figures from the Philippines relating to children exposed to infection confirmed this view. A child, as long as it remained in the house with an infective leper, was likely to get the disease, and the same was true of tuberculosis. If children in tuberculous families were boarded out, as was largely done in France under the Grancher system, they were not likely to get the infection. It was also evident that in both diseases certain cases were much more infective than others. In South Africa, out of 2,500 patients in leper asylums, nearly 700 were found not to be discharging bacilli, and from the prophylactic point of view there was no value in their segregation. He felt that there was a great deal too much segregation of non-infective leprosy, and a great deal too little segregation of tuberculous cases of tuberculosis. No open case of tuberculosis ought to be allowed to reside in a house in which there were children.

Continuing, Sir Leonard Rogers said that the route of infection, which in tuberculosis was the air passages, in leprosy was mainly the skin. He thought it possible that the high incidence of leprosy in areas of heavy rainfall might be explained by the large number of biting insects in such regions, and by the fact that their punctures of the skin were exacerbated by scratching by the victim. In this way any micro-organism on the skin might be rubbed into the tissues. He then drew attention to the climatic differences between the leprosy and the tuberculosis distribution. One exception to the close correspondence between heavy rainfall and high leprosy incidence was to be noticed in Lower Bengal, where the rainfall was high and the

leprosy rate low. The low incidence of leprosy here has been attributed to the natural segregation in this region, where the houses were built at a considerable distance from one another, not in the close aggregations of Indian villages elsewhere. On the other hand, to bear out his main argument, leprosy was low in the Deccan and in Central Madras, where also the rainfall was low. Turning to the distribution of tuberculosis, he remarked that Assam, with the highest rainfall in India, had almost the lowest tuberculosis rate; also in some other parts of the country the tuberculosis incidence did not follow the rainfall. In certain areas the construction of the land was such that, while there was no great precipitation of rain, the damp relatively rainless areas brought rain, prevailed in these continued beyond the rainy region—and in these regions the tuberculosis rate was high. It was the general rule that places with the lowest humidity had the lowest tuberculosis rate, and there was no real contradiction even in Assam, with its heavy rainfall and its low tuberculosis incidence, for here there was an area which, notwithstanding the rainfall, was, by the configuration of the land, protected from the rain-bearing monsoon currents. In brief, rain favoured the leprosy bacillus; damp winds, which did not necessarily mean rain, favoured the bacillus of tuberculosis. He pointed out that in the case of leprosy the organism was extremely difficult to cultivate, which indicated that it did not live for any length of time outside the body, and this fitted in with the theory that high rainfall created favourable conditions for the leprosy bacillus to live for a short time on the skin, and so get rubbed into any slight wound.

Surgeon Rear-Admiral Sir PERCY BASSETT-SMITH commented what seemed to him Sir Leonard Rogers's inference that where tuberculosis was abundant it protected to some extent against leprosy. It did not appear to him likely that tuberculosis could immunize a population against disease of a totally different character.

Lieut.-General Sir WILLIAM LEISKEMAN considered that there was a possible parallel to what Sir Leonard Rogers had pointed out in the case of two other organisms, themselves closely allied, though quite different from the organisms of tuberculosis and leprosy—namely, the typhoid and paratyphoid organisms. There was no laboratory evidence whatever that immunization with typhoid bacillus gave antibodies to the paratyphoid group, but his own experience in the war showed clearly that inoculation with the paratyphoid vaccine did give definite protection against the paratyphoid. As the typhoid inoculation in the army was increased, in the early days of the war, the incidence of typhoid fever fell, but so did the incidence of paratyphoid infection, and yet there was no laboratory evidence of immunization against this latter.

Sir LEONARD ROGERS, in replying to the brief discussion, said that he had worked out his figures for the distribution of tuberculosis in India, not from the statistics for the general population, which were absolutely valueless, but from the figures for the gaols, which were collected by qualified medical men. Further, he had taken the figures for ten consecutive years, and for separate areas each time. The distribution of pneumonia was quite different from that of tuberculosis, so that it was not a case of the incidence of lung affections simply. He went on to declare his absolute opposition to the unrestricted segregation of lepers. While it was too soon to speak of cures of leprosy, he had known cases remain well for ten years after having been covered from head to foot with leprosy lesions. But compulsory segregation was a stumbling-block to that early treatment which was necessary if cure was to be effected, for where there was segregation the early cases did not come forward.

*Animal Infections in the Zoological Gardens.*  
Dr. N. S. LUCAS gave an account of the infections of animals in the gardens of the Zoological Society of London. The commonest infections, he said, were those of the pulmonary and alimentary systems. Many captive animals showed extraordinarily low powers of resistance to pulmonary disease; polar bear cubs, for example, invariably died of pneumonia within a week of birth. No particular

type of mammal or bird could be said to be specially immune from or specially subject to pulmonary disease, though perhaps the larger birds came less frequently than others to the post-mortem room. The size of mammals furnished no clue to their capacity of resistance; he had seen a giraffe apparently well in the evening and dead the next morning from pneumonia, whereas the little marmoset, affected in the same way, put up a good fight for life. Animals died from pneumonia with extraordinary suddenness; he had seen a monkey die while taking a meal of rice, with some uncommon amongst mammals, and birds occasionally had pericarditis, with more or less effusion. Enteritis with mammas, birds, and reptiles alike had been a common cause of death. In healthy birds the number of colonies of *B. coli* on a plate was not large, but in diseased birds these colonies became very numerous. He believed that *B. coli* played a far more important part in the pathology of bird enteritis than it did in human enteritis. Except for bird enteritis as they would obtain in their natural haunts, and he thought it possible that a stago was reached when *B. coli* became pathogenic. Newly imported animals died of enteritis or of pulmonary infections more frequently than animals which had been longer in this country; but deaths were also very frequent among animals which had been domestic pets, and failed to adapt themselves to the new environment. Of the chronic infections the most important was tuberculosis. An idea prevailed that tuberculosis caused the bulk of the deaths among mammals in the Zoological Society's care. This was not the case; tuberculosis was a diminishing which sent up the figures. Such an epidemic occurred in the anthropoid ape house in the early part of 1924. Among mammals the apes, monkeys, and herbivora were most susceptible to tuberculosis, the carnivora were most so. Among birds the disease had diminished greatly during the last two or three years, and scarcely a case had occurred recently outside one aviary, which was somewhat ancient. One curious circumstance was the infection of a rhinoceros with bovine tuberculosis. It was difficult to make out why a rhinoceros living in solitude and with no milk in its diet should acquire the bovine type of tuberculosis. Its quarters were distant by almost the entire length of the gardens from the cattle-sheds, so that there could hardly be any question of contaminated dust. On the other hand, apes, which had milk in their diet, acquired the human type of tuberculosis. He had only once seen joint tuberculosis; this was in a dove. The tuberculosis cases were usually of long standing, but he recalled the case of a bear which had the acute pulmonary condition. He thought it would be well to view with caution the suggestion that there was any cross-infection between epidemics of pulmonary disease in the gardens and in the London streets; certain epidemics influenced rendered all mammals equally susceptible. So far as he was aware, there had never been known in the London gardens an instance of a man affecting an animal or vice versa, although in a foreign zoo tuberculosis among some animals had markedly declined after their cages had been removed beyond the range of human expectoration.

#### PITUITARY DISEASE.

A MEETING of the Section of Medicine of the Royal Academy of Medicine in Ireland was held on December 19th, 1924, the President, Dr. F. C. FORSTER, in the chair. Dr. LEONARD ABRAHAMSON showed two patients. The first was a case of Fröhlich's syndrome.

The patient, a male aged 17, was admitted to hospital for a traumatic ulcer on the leg. He was undersized and extremely stout. The obesity had come on fairly rapidly and without apparent cause three years previously. His height was 4 ft. 7½ in., weight 7 st. 13 lb.; considerable accumulation of fat on face, breasts, and abdomen; memory poor; tendency to drowsiness; voice high-pitched; skin dry, rather coarse; no hair on face or axillae; pubic hair of feminine outline; genitals infantile; blood pressure 145 systolic, 80 diastolic; temperature normal, elevated to 99° F. by injection of extract of anterior lobe of pituitary. A glucose

tolerance test showed definite diminution of carbohydrate tolerance; basal metabolic rate normal. Examination of the eyes showed some contraction of the right field of vision; no change in the fundi. A skiagraph of the skull suggested bridging over of the sella turcica by an enlargement of the anterior clinoid process.

Dr. Abrahamson discussed the diminished carbohydrate tolerance, and suggested, as an explanation for this and for the increase of blood pressure, compensatory overaction of a ductless gland other than the pituitary—namely, the suprarenal.

The second patient was a case of diabetes insipidus with symptoms of hypopituitarism.

The patient, a male aged 19, had complained for six years of thirst and polyuria. The urine looked like water; the quantity varied from 190 oz. to 360 oz. in twenty-four hours, and the specific gravity from 1001 to 1002. A skiagraph of the pituitary fossa revealed no abnormality. Besides the symptoms of diabetes insipidus the patient presented a somewhat feminine appearance. The voice was high-pitched, the skin smooth and fine; no hair on the face; no axillary hair; pubic hair of feminine distribution. Blood pressure 105 systolic. Marked improvement in the thirst and polyuria took place during injections of pituitrin 1/2 c.cm. twice daily. Pituitary gland by the mouth produced no effect.

The PRESIDENT said that about a year ago he had had a case of diabetes insipidus for which he could find no cause, but he treated the patient with pituitrin. The amount of urine passed in twenty-four hours was about 27 pints. The pituitrin had no effect when given subcutaneously or by the mouth, and removal of 7 c.cm. of cerebro-spinal fluid by lumbar puncture only increased the amount of urine passed.

Dr. T. G. MOORHEAD had only seen one patient with diabetes insipidus within the last four or five years. This was an extremely severe case in a woman aged 40. Apart from the urinary symptoms nothing else abnormal was found. He advised injections of pituitrin, and the first dose of 1 c.cm. produced such a dramatic effect that the patient at first refused to have any more. The amount of urine passed the night following the dose was under a pint, whereas previously it had been measured by the pailful. A subsequent course of injections was given, and as long as it was given the patient remained better, but she refused to go on with it and relapsed. Pituitary gland substance by the mouth had absolutely no effect, and a lumbar puncture was refused. The patient died about a year after he had first seen her.

Dr. H. F. MOORE, referring to the second case shown by Dr. Abrahamson, said that the fact that the basal metabolic rate was normal removed any suggestion of thyroid deficiency, and therefore he did not think much good would result from the giving of thyroid extract. To use it would only be treating the obesity, and not treating the fundamental condition. The fact that the boy's blood pressure was normal, while the sugar utilization was increased, might be explained in several ways—(1) he might be suffering from diabetes mellitus in addition to the other condition, and (2) hyperadrenalism might be present as well as the anterior pituitary trouble, or (3) the anterior lobe might be hypofunctioning and the posterior lobe hyperfunctioning.

Dr. R. H. MICKS referred to a girl of 17 who had always been childish; for about two years before he saw her she had suffered from intense headaches, had optic neuritis, and looked very like a case of Fröhlich's syndrome.

#### Clinical Blood Cultures.

Dr. J. H. POLLOCK read a paper on blood culture in clinical medicine, showed lantern slides of apparatus, and discussed the question of technique. He emphasized the need for diluting the patient's blood, to remove any bactericidal bodies present; a reasonable quantity of blood should be employed. Having detailed a series of cases in which streptococci were recovered from the blood, he concluded that blood culture was a valuable clinical supplement for both diagnosis and prognosis.

Dr. T. G. MOORHEAD thought that nobody who had been through a typhoid epidemic would doubt the value of blood cultures in making an early diagnosis of typhoid or paratyphoid fever. He regarded blood culture examinations as a part of ordinary routine clinical work.

Dr. R. J. ROWLETTE considered that the cultural examination of the blood was a very helpful part of clinical diagnosis; it should never be neglected in cases of pyrexia, even if in a fair proportion of cases a negative result was obtained. Owing to the improvement in technique of late years positive results were obtained in a great many cases in which one would not have succeeded ten years ago. He thought positive results were rare except in furunculæ, septicaemia, when a positive result was almost uniformly obtained. A positive blood culture in a maternity case meant a very bad prognosis. Very few patients recovered if streptococci were found in their blood, but he knew of a case in which *Staphylococcus aureus* had been found and the patient recovered. He had found autogenous vaccines beneficial in puerperal cases. He thought that as the method of blood culture improved still further it would be possible to get positive results in cases such as chronic arthritis, which he felt was due to some very persistent though not active infection.

Dr. H. F. MOORE, from his experience of pneumonia and typhoid fever, could not agree that positive blood cultures were only obtained when hyperpyrexia was present. The agar plate method, when correctly employed, gave a very good numerical idea of the degree of septicaemia; pneumonia with a rising degree of septicaemia was almost certainly fatal.

Dr. G. DE BENCA said that when doing blood cultures he used a small bottle with a glass stopper and a few bits of broken glass at the bottom; he used 50 c.cm. of titrated broth, and always put the blood into the broth at blood heat. He mentioned several recent cases in which pure cultures of pyogenic organisms were obtained from the blood and an autogenous vaccine had been given with good effect.

Dr. L. ABRAHAMSON suggested that blood cultures were not done often enough in the same patient. The writer of a recent article had done a blood culture twenty-one times in one patient before isolating an organism. In one group of cases all the symptoms of septicaemia were present, but the blood cultures were always negative; in another group with the same symptoms the culture was positive. He had observed that patients with septicaemia from whose blood stream no organism could be isolated seldom recovered.

Dr. R. H. MICKS, like Dr. Moore, had found the agar method, in combination with broth cultures, helpful in excluding skin contaminations. He drew attention to the value of doing subcultures from the original culture.

#### BONE SURGERY.

The second meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on January 8th, with the President, Dr. SINGLETON DARLING, in the chair.

Mr. A. B. MITCHELL read notes, illustrated by lantern slides, on some modern methods of bone surgery. The first was a case illustrating the life-history of a bone graft, with slides over a period of six years after removal of some six inches of the tibia for a growth. Another series of slides showed the results of the treatment of spiral fracture of the tibia by tying silver wire round both ends of the fracture and tightening, after putting the fragments in position. The third series showed the result of a modification of Macewen's and Jones's operation for extreme knock-knee, in which the lower fragment of the femur was completely separated from the upper, and placed in direct axis of the limb; the fear of sepsis from the necessarily large wound was unfounded. The fourth series of slides showed excellent results following arthroplasty of elbow-joints.

Professor SINCLAIR, discussing the paper, said that in former times amputation was occasionally performed in cases of simple spiroid fracture of the tibia owing to the very bad results that too often followed the ordinary treatment by splints.

Mr. IRWIN, Mr. HOWARD STEVENSON, and Mr. CRYMBLE also congratulated Mr. Mitchell on his paper and his excellent results.

Dr. SAMUEL SIMMS read a paper on the principles and practice of the Father of Medicine. The paper dealt with the state of medicine during the famous epoch in which Hippocrates lived, the traditional family custom of inheriting occupation, the health shrines, and the collection of dicta or sayings. He then examined, and gave extracts from, some of the writings handed down as the writings of Hippocrates, and showed what an enormous advance was portrayed.

The PRESIDENT, in thanking Dr. Simms for his interesting and instructive paper, expressed the hope that more would be heard from him in this department of medicine.

### EDINBURGH OBSTETRICAL SOCIETY.

At a meeting of the Edinburgh Obstetrical Society on December 10th, 1924, a paper on chronic pelvic pain in relation to neurasthenia (printed in full at page 100) was read by Professor RANKEN LYLE.

Dr. DOUGLAS MILLER read a communication entitled "A study of two cases of Krukenberg tumours of the ovary." In the first case the patient had been operated on for gastric carcinoma twelve months after ovariectomy; in the second case the ovarian tumour was associated with an irreparable malignant tumour of the bowel. In both cases the ovarian neoplasm was found to correspond more or less closely in its microscopical appearances with Krukenberg's original description, the groundwork of the tumour consisting of a fibrosarcomatous reticulum in the meshes of which large "signet-ring" epithelioid cells were present. Dr. Miller referred to the various interesting pathological questions of interest which a study of the Krukenberg tumour provoked; the possibility of the tumour arising as a primary growth in the ovary was discussed, and the problem of explaining the combination in its structure of malignant connective tissue and epithelial elements was shortly considered. The communication was illustrated with lantern views.

Dr. CHASSAN MOIR read a paper entitled "An investigation of the clinical effects of laevo-rotatory and dextro-rotatory hyoscine," based on his clinical experience of twenty-seven cases of labour, of which twelve were treated by dextro-rotatory hyoscine and fifteen by the laevo-rotatory compound. The system of dosage was similar with both drugs—namely, morphine sulphate gr. 1/6 and hyoscine hydrobromide gr. 1/100 at the beginning of labour, followed by a further dose of hyoscine gr. 1/200 an hour after, and then gr. 1/450 every succeeding hour. As a result of his investigations it was found that the dextro-rotatory compound was practically inert as regards "twilight sleep," no amnesia, no drowsiness, and no loss of intelligence following its administration, whereas the laevo-rotatory produced complete amnesia in twelve cases and partial in three. It would seem, therefore, that it was the laevo-rotatory compound which produced the narcosis, and Dr. Moir urged that all hyoscine compounds should be standardized, as in Germany. It would then be known what quantity of the laevo-rotatory compound was present, and the results of administration would not be so doubtful as they were now when no standardization was required.

A series of interesting specimens were shown by Dr. A. E. CHISHOLM; and the President, Professor B. P. WATSON, showed a consecutive series of ovarian cysts, which were found to be malignant on examination, and on this account the necessity for removal of such cysts without a preliminary tapping was strongly advocated.

### BRONCHOSCOPY AND OESOPHAGOSCOPY.

At a meeting of the Brighton and Sussex Medico-Chirurgical Society held on January 1st, the President, Dr. E. F. MAYNARD, in the chair, Mr. D. A. CROW read a paper on peroral bronchoscopy and oesophagoscopy.

Mr. CROW outlined the work of Chevalier Jackson and his associates in the bronchoscopic clinic in Philadelphia; lung abscess drainage, the diagnosis and treatment of neoplastic, cicatricial, and spasmodic stenosis of air and

food passages, and foreign body problems were briefly described. As an illustration of the immensely detailed study necessary for the removal of a foreign body, Dr. Jackson's methods of removing a point-up safety-pin were reported. Mr. CROW laid stress on the importance of distinguishing between a foreign body potentially or actively obstructive to the air passages or vegetable substances, such as nuts, which caused intense reaction, and less urgent conditions such as the non-obstructive metallic bronchial foreign body, which was often overlooked (in the absence of a radiogram) in cases diagnosed as phthisis or bronchiectasis.

The PRESIDENT referred to the rapidity of recovery of an abscess after the removal of the foreign body concerned. He believed that bronchoscopy was a very valuable aid to diagnosis in cases where no organic disease of the lung could be found by clinical methods, and in cases of lung abscess.

Mr. A. J. HUTCHINSON thought oesophagoscopy should be employed more frequently in cases of dysphagia.

Dr. L. A. PARRY asked if Mr. CROW advocated that swallowed foreign bodies which had passed into the stomach should be removed by the mouth. Of twenty cases in his experience only in one case—that of a latch-key remaining in the stomach seven days—was it necessary to operate abdominally; the other foreign bodies all passed per rectum.

Mr. H. N. FLETCHER asked what were the possibilities of operation by bronchoscopy on abscesses of the lung, which were usually situated in the lower lobe.

Mr. D. A. CROW, in reply, referred to the rarity of foreign bodies being coughed up from the bronchi (2 per cent. only). Gastroscopy was not required for foreign bodies in the stomach, and abscess of the lung could be dealt with very successfully by bronchoscopy.

### Eradication of Tonsils and Adenoids.

Mr. J. R. GRIFFITH read a paper, illustrated by lantern slides, on the eradication of diseased tonsils and adenoids. He described Waugh's method of removing tonsils by means of blunt dissection. He claimed that the method was clean, accurate, and almost bloodless; that it avoided injury to the pillars of the fauces with their contained muscles, and that it also avoided the danger of aspiration of blood into the larynx and trachea. It was important to make the primary incision in the right place so as to expose the capsule at once. The blood vessels were identified entering the capsule before they were divided, and bleeding was completely stopped by gauze pressure over the divided ends of the vessels. The technique of the last part of the operation was important, ensuring the removal of the whole of the lingual pole and at the same time avoiding injury to the base of the tongue. The adenoids were then removed with a La Force adenotome, an instrument on the guillotine principle. The window was curved to fit the superior and posterior walls of the nasopharynx, and the cutting part was furnished by a flexible steel blade running in grooves in the window frame. This instrument cut through the adenoid attachment cleanly without tearing the mucous membrane. As a rule bleeding was very slight, ceasing after the nasopharynx had been mopped out two or three times. Mr. Griffith claimed that the results obtained by these methods were superior to those he had obtained previously by enucleating with Sluder's reversed guillotine.

Mr. A. J. HUTCHINSON preferred the reversed guillotine for children under 12 years of age. The disadvantages of Waugh's operation were the deep anaesthesia required and the length of operation. Also, if the incision was not made in the exact line, more damage was done to the pillars than by the reversed guillotine. Mr. D. A. CROW always used Waugh's method in children and adults, but did not stitch the pillars of the fauces. Mr. F. E. FEILDEN stressed the importance and difficulty of getting into the right layer.

Mr. GRIFFITH, in reply, said that there was less danger in deep anaesthesia by ether than in light anaesthesia with the possibility of laryngeal spasm. Bleeding might be very serious when the reversed guillotine was used.

Dr. A. W. WILLIAMS showed a case of pityriasis rosea involving the whole trunk and limbs down to the elbows and knees. The rash had cleared, but the areas were left deeply pigmented, owing to arsenic, which had been administered in small doses before the case came under his notice.

## Rebiefus.

### THE NERVOUS PATIENT.

DR. MILLAIS CULPIN has written a book on *The Nervous Patient*,<sup>1</sup> designed to meet the needs of the family practitioner in dealing with a type of case which bulks so largely in his practice. The author points out that psycho-pathology offers explanations and methods of treatment for nervous troubles which have hitherto been the reproach of medicine and the hunting ground of the irregular healer. He feels that it can throw light upon old problems and suggest new ones, and that to the practitioner it offers an increase of clinical opportunities. Among the subjects considered are: psycho-analysis; repression and suggestion; the physical relationships of the minor psychoses; the principles of diagnosis; the mental factors in asthma, exophthalmic goitre, and gynaecological conditions; postural deformities and the psychological aspects of the effort syndrome; and simple principles of treatment. Mr. W. S. Inman contributes a chapter on eye symptoms, and Dr. Stanford Read another on the major psychoses in general practice.

Dr. Culpin suggests that the phrase "minor psychosis" might be used for the cases now included under the term "neurosis" or "psycho-neurosis." He recognizes that an objection might be made to this proposal on the ground that it might frighten the public, who now draw such a sharp line between "mental disease" and "nervousness." He thinks, however, that a trend of psychiatry is to educate the public towards the removal of the stigma that attaches to mental disease, and that the present terminology is pandering to the conception of a stigma. From the standpoint of verbal accuracy, Dr. Culpin's suggestion has much to commend it. A psychasthenic is certainly not suffering from "nerves," and his symptoms cannot be anatomically localized in the nervous system; the disease manifests itself by disturbances in psychological rather than physiological functions, and this holds good even if the abnormal attitude of the patient be associated with physical changes in the organism. Thus general paralysis does not cease to be described correctly as a major psychosis because its symptoms are the outcome of structural changes, or an influential depression cease to be a minor psychosis because its symptoms can be correlated with a toxic state of the organism. Though, strictly speaking, the term "psychosis" means any concrete psychical process, element, or act, it has come to be associated with abnormal mental reactions, and for this reason it is quite properly applied to both mild and severe psychical disturbances. An obsession is obviously quite as much a psychotic manifestation as a hallucination. French psychiatrists find it convenient to use the phrase *petits mentaux* to cover the cases to which "minor psychoses" might be applied, so that the author's suggestion is not without a precedent.

### OPERATIVE DENTISTRY.

In the *Text-Book of Operative Dentistry*,<sup>2</sup> edited by Professor C. N. Johnson of Chicago, we have the views and practice of many of the most eminent dentists of the United States of America on their specialties of dental work. Perhaps the most interesting chapter to the general practitioner is that on the application of the Roentgen ray to dentistry. He will possibly be comforted to learn that the correct interpretation of dental x-ray pictures is often as difficult to the dentist as to himself. The writer of the chapter is outspoken in his criticism of bad work, from which only mistaken diagnoses can be made. "Disease itself can never be recognized upon a film" is one of the author's dicta; and he is of opinion that "to take a skiagraph, and charge for it, for the diagnosis of pyorrhoecia, is just robbery." He has, however, written a most interesting and well illustrated chapter indicating the limitations and difficulties as well as the usefulness of x rays as applied

to dentistry. We may, perhaps, be allowed to ask, where is the missing tooth in Fig. 501?

Nearly a third of the book is devoted to "orthodontia," and the medical mind will be chiefly struck by the fact that "fixed appliances" bulk so largely in the treatment of "regulation cases." It will at once be asked, how can these things be kept clean? When discussing thumb-sucking, the writer of this section suggests the use of an aluminium mit fastened to a sleeve tied on the child's arm. The hollow aluminium ball is large enough for the child's hand to move freely inside it and too big for its mouth. It should be perforated for ventilation.

Pyorrhoecia is dealt with in some twenty pages, and given its true position as a local disease amenable to local treatment—"systemic conditions or a constitutional diathesis without local irritation do not destroy the integrity of the gingival border." The writer's method of treatment is, in brief, by sealing and subsequent cleanliness; but it may be doubted whether the advice not to touch the pockets for sixty or ninety days for fear of disturbing "the plasma out of which repair comes" is sound. Probably no reunion of gum flaps to denuded tooth ever takes place, and the undisturbed plasma runs the risk of becoming only a breeding ground for bacteria.

The writer who discusses replantation of teeth (an operation which is not to be confounded with transplantation of teeth from one mouth to another) notes that x-ray pictures seem to show that the periodontal membrane is destroyed in these cases, and that this leads to immediate apposition of bone to root; but he publishes an x-ray picture of a molar, replanted nineteen years before, taken shortly before its final extraction, which, he claims, shows that the periodontal membrane survived the operation of replantation. The hope is expressed that we shall some day learn to perform the operation without destroying the periodontal membrane, when replanted teeth will last indefinitely. We may be allowed to suggest that the x-ray appearances could be well explained as the result of absorption of bone leading to the final undoing of the tooth.

Those who have used the dental engine and burr in operating for the extraction of an impacted tooth know well how easy it is to injure the parts by overheating of the burr, and how blood and saliva obstruct progress. For use in cases operated on under local anaesthesia the writer on tooth extraction describes a method of irrigation with cooled water, delivered by one tube of a two-way catheter and removed by suction through the other, which, he says, effectually removes these difficulties. We note that so-called surgical extraction receives no mention, and that enucleating of sockets is only advised where obvious granulomata exist or bony edges need smoothing: "teeth affected by pyorrhoecia are not difficult to extract, and their sockets require no further treatment of any kind."

In a short review for medical readers we cannot pretend to note every point that arrests attention, but one general criticism we may venture—there is an exuberance of verbosity in some parts which, though adding to bulk, in no wise adds to value. This said, we can only record our opinion that Professor C. N. Johnson's *Operative Dentistry* maintains the high standard in this, its fourth, edition which we have learned to look for in all his work. It is a book that should be in every reference library, and every section will well repay close study.

### AN ENCYCLOPAEDIA OF PEDIATRICS.

THE fourth volume of the new edition (third) of PFAUNDLER and SCHLOSSMANN's *Handbuch der Kinderheilkunde*<sup>3</sup> has now been published. A review of the first two volumes was published in the *JOURNAL* of February 9th, 1924 (p. 240). It remains now to give some account of volumes iii and iv.

Volume iii deals with diseases of digestion, of respiration, and of the circulation. The large and complicated subject of nutritional disorders in infancy is expounded in a long article by the late Professor Niemann, while the closely related subjects of metabolism in nutritional disorders, and of the bacteriology of the digestive tract, are dealt with

<sup>1</sup> *The Nervous Patient*. By Millais Culpin, M.D., F.R.C.S. (Eng.). London: H. K. Lewis and Co., Ltd. 1924. (Demy 8vo, pp. vii + 366. 10s. 6d. net.)

<sup>2</sup> *A Text-Book of Operative Dentistry*. By various authors. Edited by C. N. Johnson, M.A., L.D.S., D.D.S., M.D.S., F.A.C.D. Fourth edition, revised and enlarged. London: William Heinemann (Medical Books), Ltd. 1923. (Med. 8vo, pp. xvi + 1136; 1144 figures. 50s. net.)

<sup>3</sup> *Handbuch der Kinderheilkunde*. Herausgegeben von Professor Dr. M. von Pfaundler und Professor Dr. A. Schlossmann. Vols. iii and iv. Third edition. Leipzig: F. C. W. Vogel. 1924. (Imp. 8vo; vol. iii, pp. 773, 15 plates, 185 figures; vol. iv, pp. 789, 8 plates, 163 figures.)

by Professors Meyer and Uffenheim. It is interesting to note in Niemann's paper the trend of opinion towards a simpler clinical classification of the dyspepsias of infancy. The influence of Czerny and Keller remains predominant, and their teaching as to constitution, food injury, and infection is accepted as the pathological basis of the subject. But a simpler and more rational account is given of the abnormal bacterial processes in the intestinal canal of dyspeptic infants, the alternative predominance of sugar fermentation and of protein decomposition determining in one case the green acid stools of diarrhoea, and in the other the pale, putrid, soapy stools of marasmus (or, in Finkelstein's terminology, decomposition). The ground is thus prepared for a clinical grouping of the cases into those with diarrhoea of varying grades of severity and those presenting malnutrition. The treatment of these conditions is also essentially governed by the state of the stools and the evidence they yield, either of excessive fermentation or of excessive putrefaction. All this is a real advance towards simplicity and intelligible pathology and therapeutics founded on reason. It is to be hoped that Finkelstein's vocabulary, which has really confused an obscure subject by attaching to it long and unintelligible names. In the same section, in the chapter on the peritoneum, Professor Birk gives a full and clear account of pneumococcal peritonitis, both in its acute and chronic forms, and the volume is completed by long and well illustrated accounts of respiratory and circulatory disease.

Volume iv begins with diseases of the uro-genital system, which are described at great length by Noegerrath and Eckstein. This chapter is prefaced by an index of chapter headings, an aid to reference which is too seldom employed in the other volumes and sections. Diseases of the suprarenals and chromaffin system, organic disease and functional disorders of the nervous system, a separate chapter on meningeal conditions, and diseases of the locomotory system make up the remainder of the volume. An elaborate general index to all four volumes is provided and completes this so-called handbook, which is really an encyclopaedia of the subject.

On surveying again the wide field of medicine covered by this book, we are impressed by the space occupied by physiology, hygiene, and preventive medicine. Another impression is the strong position which the subject of pediatrics has won in German medicine. That place of honour has been built up by adequate teaching of the subject and zealous research in every important medical school, and by the communication of that teaching and research through special societies and journals. Pfaunder and Schlossmann's book is something more than the combined effort of two skilful editors and many learned contributors: it is the natural and choice fruit of a sound system of growth, in which teaching and study have reacted upon one another, the teacher communicating the ardour of research to the student, so that the tree of knowledge grows and bears fresh fruit.

### POST-MORTEM ROOM TECHNIQUE.

The procedure tabulated by Dr. BÉLA HALPERT in his work on post-mortem examination,<sup>4</sup> is at an opposite pole to that often pursued in this country. An assistant is set to lay open the body and remove the viscera, which are only then examined, the examiners being satisfied when some change is found which will pass as a cause of death. In a preface Dr. Gnox states that, as an extension of the method ascribed to Rokitansky for the examination of the three cavities, the several organs are first inspected in position together with their vascular supply. After the removal of the organ glands of the region are observed. The examination of each of the three cavities proceeds in steps—first the inspection of the surface and of the orifices, then due note at each stage in course of laying open the cavity, and in exposing the organs.

<sup>4</sup> *Pathologisch-Anatomische Sektionsmethode: Nach den Grundsätzen des pathologischen Institutes der Prager Deutschen Universität.* Herausgegeben von Dr. Béla Halpert. Mit einem Geleitwort von Professor Dr. A. Gion. Vienna: Julius Springer, 1924. (Demy 8vo, pp. vii + 48. Dollar 0.50)

In the case of the head the examination commences with the surface of the scalp, face, chin, ears, nose, mouth, then the laying bare of the skullcap. Observation of the skullcap in the course of removal and of the exposed dura mater is followed by the reflection of the latter, and the inspection of the arachnoid, pia mater, surface of the brain, and the entry of the cerebral arteries into the fissures. Whilst removing the brain the cranial nerves and circle of Willis are noted as cut across. The brain being removed for systematic examination, then follows the laying open of the venous sinuses, exposure of nerve ganglia and of the pituitary body, base of skull, aural and nasal sinuses, nasopharynx, nose, mouth, fauces, and pharynx from above, concluding with the large blood vessels and lymphatic glands underneath the skull. Examination on similar lines is described for the root of the neck and chest, for the abdomen and pelvis. Such a systematic method is likely to discover changes to which can be attributed the cause of death.

### HERNIA.

In presenting the most important features of the anatomy, etiology, symptoms, diagnosis, differential diagnosis, and prognosis of hernia, Dr. L. F. WATSON of Chicago has succeeded very well in his object. One of the chief features of this book, *Hernia*,<sup>5</sup> is that an historical sketch is prefixed to the more important chapters. The anatomy is dealt with in detail, and the author has clearly been at great pains to study the literature of the whole subject; the bibliography given shows the undertaking has been very laborious. Not all the operations for hernia are described; details are given only of those to which he is partial; but those that are less generally used, though invaluable in certain cases, are outlined. The book is abundantly and clearly illustrated, and the anatomical details and operative technique well depicted.

The first chapter, on the general consideration of hernia, is a good introduction to the subject; the classification is based on the same lines as those in our own textbooks. Many of the old theories about the mechanism of strangulation are quoted, but not a few are at the present time only of historical interest; the author concludes that the theory of elastic strangulation explains the majority of cases. He advises primary resection as the treatment which should be employed whenever possible, as both the immediate and late mortality rates are lower after it than after operation to produce an artificial anus. The best method, he considers, is to close the divided ends and perform lateral anastomosis. End-to-end anastomosis is his second choice. In cases of extreme urgency the anastomotic button should be employed or an artificial anus formed. The distended afferent loop of bowel that lies above the constriction should always be emptied. In grave cases lateral anastomosis above the strangulation is sometimes advisable. When no assistant is available end-to-end anastomosis by means of the basting stitch, and recommended, although the text is not precise in describing the ultimate fate of the basting stitch. In the chapter on the anatomy of inguinal hernia some interesting figures are given showing the formation of oblique inguinal hernia. All direct hernias, it is said, belong to the acquired variety. Several alternative methods for treating this type are given, but that favoured is Downe's operation, where the sheath of the rectus is opened and united to Poupart's ligament. The internal oblique is similarly tethered, where these structures passing deep to the cord. The edges of the external oblique are then overlapped, giving three separate layers instead of two, as in the Bassini operation. Unilateral and ventral hernias are well described, although we could wish that more detail had been given about the use of filigrees, and expresses a strong partiality for free fascial transplants. The book concludes with a satisfactory description of all the uncommon types of hernia. It is

<sup>5</sup> *Hernia.* By Leigh F. Watson, M.D. London: H. Kimpton, 1924. (Sup. roy. 8vo, pp. 650; 232 figures. 52s. 6d. net.)

interesting to note that the author prefers the abdominal route for dealing with diaphragmatic hernia.

This book should fill the same place in America as the book on the same subject, by Mr. Jonathan Hutchinson, occupies in this country. Both are excellent, although Dr. Watson does not to the same extent share Mr. Hutchinson's enthusiasm for the use of kangaroo tendon in operations for hernia.

#### IMPERIAL COLLEGE OF AGRICULTURE, TRINIDAD.

SIR ARTHUR SHIPLEY is probably the best living writer of popular books tinted by accurate scientific knowledge. In the *Minor Horrors of War*—a series of articles chiefly on noxious insects which he wrote for this JOURNAL, and afterwards collected into two volumes—the tint was deeper than in his new book, *Islands: West Indian—Aegean*.<sup>6</sup> He went to the Greek islands for fun as a guest on Mr. J. Pierpont Morgan's yacht, but he contrived to land at Cos to see the remains of the Temple of Aesculapius and "the venerable and gigantic plane under whose shade it pleased us to think, as the pious islanders think, that the greatest of all physicians, Hippocrates, taught."

The object of the visit to the West Indies was to give a helping hand to the Imperial College of Agriculture which has been established in Trinidad. It has grown out of the Imperial Department of Agriculture, established by the Colonial Office in 1899, with headquarters in Barbados. Its object was to restore the sugar industry and to encourage others; it has done much to introduce economic plants from other lands. A committee appointed by Lord Milner when Colonial Secretary in 1919 recommended the establishment of a college, and selected Trinidad as the most suitable island. It was established in temporary buildings, but a permanent institution is now approaching completion. The staff of the Imperial Department of Agriculture have become professors in the new College, and the promise of good work in future is very great. Sir Arthur Shipley went to many of the other islands, about each of which he has something interesting to say. He gives a short account of the control of yellow fever, illustrated by an excellent diagram showing the rapid reduction since 1900 in the number and extent of the areas involved. Other chapters have other illustrations of a less serious kind. Barbados is one of the most densely populated areas on the face of the earth; it is the healthiest of the West India islands—in fact, a health resort. It has a porous soil (coral rock) and no anopheles mosquitos. The stegomyia is found, but is kept in subordination.

#### A DOCTOR IN THE DESERT.

THE lesser conflicts that led up to it are apt to be forgotten in the general chaos and upheaval caused by the great war. One of these was the Italian expedition to Tripoli at the end of 1911. It was an unprovoked attack upon a weak State, and it added little lustre to the arms of our late allies. Tripoli was a purely Moslem province of the Ottoman Empire, governed directly from Constantinople. Unhappily, the Sultan had for a long time neglected the navy, and the land forces were hopelessly inadequate for the defence of the country. In spite of this the Turks, with the aid of the Arabs, maintained a gallant resistance until October, 1912.

The British Red Crescent Society was founded by two distinguished Indian gentlemen to succour the Moslem victims of war. Under the flag of this organization Dr. E. H. GRIFFIN spent several months in Tripoli, and his experiences are related in *Adventures in Tripoli*.<sup>7</sup> It is only natural that he should take a view very favourable to the Turks and Arabs, whom he found invariably hospitable. In a prefatory note we are told that the present Italian Government is administering the country in generous fashion, so the change is probably for the better. As might be expected, the services of a European doctor were always in request, and the author was constantly travelling by

horse or camel from one place to another, attending to wounded Arabs, distressed Turks, beggars, and village folk. A cheerful disposition and a sense of humour carried him through hunger and thirst, scorching heat and bitter chill, and he soon found an appetite for the unsavoury dishes of the Arabs. A sketch map would have been a useful addition to the volume.

#### ANNALS OF MEDICAL HISTORY.

THE third number of volume vi of the *Annals of Medical History*<sup>8</sup> has on its cover the portrait of Thomas Sydenham, as is appropriate in the year which has seen the celebration of the three hundredth anniversary of his birth, and the editor has written a note on the "English Hippocrates." The frontispiece represents Ignaz Philipp Semmelweis, and shows a resemblance to the late Prince Consort. In his interpretation of the life and work of this famous pioneer Dr. P. M. Dawson of Madison, Wisconsin, expresses enthusiastic appreciation and gratitude for the great discovery connected with Semmelweis's name. Captain F. L. Pleadwell gives an account of Elisha North (1771-1843) and his *Treatise on a Malignant Epidemic Commonly Called Spotted Fever*, supplemented by information derived from a bundle of some sixty slips of manuscript which were intended for a second edition. This edition never materialized, but after all this is perhaps not a matter for great regret, as he apparently intended to put forward the view that cholera and cerebrospinal fever were varieties of a new disease complex, "malignant (or congestive) asthenia." A hitherto unpublished letter of Sir Thomas Browne, written in 1658 to Sir William Dugdale, is reproduced by Dr. Eli Moschowitz, and in this connexion it may perhaps be pointed out that in the *Scottish Historical Review* for October, 1921, Professor T. K. Monro made public another unpublished letter written to the same correspondent in 1659; both these letters deal with the same subject—namely, the drainage of marshy land. Under the title "The Siamese Twins of Española" Drs. A. Peña Chavarria and P. G. Shipley describe, from Oviedo's *Historia General y Natural de las Indias*, the first necropsy performed by white men in the Western hemisphere; it was on two nine-days-old twins born in 1533, "each of whom would have been a beautiful woman"; the reason for the examination was not medical in origin, but to satisfy the priest whether there was one soul or two, and perhaps this is the only necropsy ever undertaken to study the soul of the deceased. The twins were formed from a single ovum before the brain, heart, or circulation had appeared; Johanna and Melchiora, indeed, just escaped being a pair of ordinary single-ovum twins. In a really charming essay Dr. J. W. Courtney of Boston relates the life and labours of Gabriel Nauvé (1600-1653), doctor of medicine, physician in ordinary to Louis XIII, and librarian to Cardinal Mazarin; "it is more than probable," we are told, "that his treatment of that monarch was of the absent variety"; he lived only for books, bought them by the yard, and opened the doors of the first public library in France. Dr. Tenney L. Davis writes on the neglected evidence in the history of phlogiston, with observations on the doctrine of forms and the history of alchemy. Dr. M. Carlton, in his fourth instalment, concludes the history of medicine in Lower Canada, and the articles will no doubt be collected into a book.

#### NOTES ON BOOKS.

IN his little book, which in the English version has the title *How to Prolong Life*,<sup>9</sup> M. JEAN FINOT, the author of a work on the philosophy of longevity, maintains that by observation of certain rules of mental, moral, and physical hygiene man ought to live at least 150 years, and that without accidents or hereditary disease he kills himself if he dies before that age. Several examples of longevity from history are quoted. The premature death of Metchnikoff at the age of 71 is attributed to his not having put into practice himself his rules of elementary hygiene for attaining old age. The translation is good.

<sup>6</sup> *Islands: West Indian—Aegean*. By Sir Arthur E. Shipley, G.B.E., F.R.S., Master of Christ's College, Cambridge. London: Martin Hopkinson and Co., Ltd. 1924. (Cr. 8vo, pp. xii + 140; illustrated. 6s.)  
<sup>7</sup> *Adventures in Tripoli: A Doctor in the Desert*. By Ernest H. Griffin, D.S.O., M.C. London: Philip Allan and Co. (Demy 8vo, pp. xii + 238; 64 illustrations. 10s. 6d. net.)  
<sup>8</sup> *Annals of Medical History*, September, 1924, vol. vi, No. 3. Edited by Francis R. Packard, M.D. New York: Paul B. Hoeber, Inc.; London: Baillière, Tindall and Cox. 1924. (8½ x 12½, pp. 245-362; illustrated. Subscription in Great Britain, £2 2s. for four numbers.)

THE MEDICAL RESEARCH COUNCIL.  
ANNUAL REPORT.

(Concluded from page 88.)

## PHOTOTHERAPY.

Dr. R. G. BANNEFMAN, at Montana, Switzerland, has found that a sunbath which raises the general temperature is followed by an increase in the number of blood platelets; the same effect is produced by a hot-water bath; heat rather than light appears, therefore, to be the effective factor. The number of platelets was found to be reduced in such affections as nasal catarrh, influenza, and measles, but much increased in chronic pulmonary tuberculosis. Dr. Bannefman has now been appointed research pathologist to the Lord Mayor Treloar Hospital at Alton, where he will be associated with Sir Henry Gauvain in studying the use of heliotherapy in surgical tuberculosis and other conditions. Dr. D. T. Harris, at University College, London, investigating the part played by pigment in determining the effects of light upon the rate of chemical change in the body, has found that the respiratory function of the blood is enhanced by exposure to ultra-violet and luminous radiation in conjunction with Professor Leonard Hill, has investigated the effects of exposing the skin of man and of animals to ultra-violet light and other forms of radiant energy. It was found that the bactericidal efficiency of the subject's blood was raised by exposure to the rays from a carbon arc or mercury vapour lamp, as well as by certain heat rays; similar improvement followed exposure to the Alpino sun in winter. It is suggested that this improved action of sunlight upon tuberculosis and other infections. In agreement with clinical experience, it has been shown experimentally that therapeutic irradiation must be carefully graded, since extensive exposures cause deterioration of the blood in a striking degree.

## MALIGNANT DISEASE AND RADIOLOGY.

At Cambridge and St. Bartholomew's Hospital, Mr. T. S. P. Strangeways, Dr. M. Donaldson, Dr. R. G. Cantliffe, and Dr. F. L. Hopwood have continued their investigations into the effects of x rays and radium irradiation on tissue cells growing *in vitro*, paying special attention to the general biological effects and to the intensity and duration of exposure required to cause immediate death. They have studied the effect of large doses, which, though insufficient to cause immediate death, produce cytological changes which may eventually prove fatal; they have also investigated the possibility of establishing complete or partial immunity of the cells to the action of x rays and radium irradiation. At King's College Hospital, Dr. H. A. Colwell, Dr. R. J. Gladstone, and Mr. C. P. G. Wakeley, studying the action of radiations on chick embryos, have again observed cell proliferation in the foetal membranes, and have found indications of increased cell division in the neutral ectoderm. Dr. Colwell, Mr. Wakeley, and Dr. M. Sydney Thomson have found that irradiation of the tadpole skin in the presence of colloidal silver gave rise to marked hypertrophy of the epidermis, accompanied by definite syncytium formation. Other colloids, including those of copper, selenium, and gold, have also been tested, and it appears that the characteristic radiations from these different agents have different effects upon the epidermic cells.

The discovery that cancer was accompanied by a reduction in the cholesterol content of the blood led to the study of the factors regulating the production of this metabolic product, and Mr. A. N. Currie is engaged in biochemical work in Glasgow in this connexion. Sunlight seems to play an important part in the elaboration of cholesterol from simple tissue constituents. His results will shortly be published, and also researches dealing with coal tar in the production of cancer. Mr. W. B. Gabriel, at St. Mark's Hospital, has traced 124 cases of perineal excision of the rectum for carcinoma since 1910. Of these 22 did not

A book honoring the title of *The Infant and Young Child* has been written by three teachers of pediatrics at the Harvard Medical School—Drs. JOHN LOVETT MORSE, EDWIN T. WYMAN, and LEWIS WEBB HILL. There is very good material in the book, though not always well arranged, but it is difficult to see the necessity of yet another book on this subject, especially when there is set forth much that is at variance with the most generally accepted modern teaching—for example, the table for the first nine months after birth, showing the intervals between feeds, suggests six changes during the period. Good advice is given on the choice and treatment of a wet-nurse, who is apparently often employed by New England mothers. A chapter devoted to judicious use of infants deals thoroughly with the causes and treatment of this trouble. In the latter part of the book, which deals with the feeding and training of older children, appear many tables of foods and recipes, but there is much with which pediatricians in general would disagree—for example, green vegetables are forbidden until the child is 2 to 2½ years old; and "the saying that 'an apple a day keeps the doctor away' has been a great boon for those physicians who specialize in the diseases of children," if it is to be taken in the sense in which it appears to be intended, will not gain general approval. The unusual advice is given that when a new article is introduced into a child's diet, and he is unwilling to eat it, his nose should be held in order to make him swallow it! The authors do, indeed, add that such an article should not be given too often.

*The Infant and Young Child: Its Care and Feeding from Birth until School Age. A Manual for Mothers.* By John Lovett Morse, A.M., M.D., Edwin T. Wyman, M.D., and Lewis Webb Hill, M.D. Philadelphia and London: W. B. Saunders Company, 1923. (Large crown 8vo, 1p. 260; 15 figures. 8s. 6d. net.)

## MEDICAL AND SURGICAL APPLIANCES.

*A Suspension for the Scialytic Light.*

The scialytic light is a French invention for the illumination of the field of operation which is coming into use in this country. Sir Hamilton Ballance has been good enough to inform us that his experience of this light is satisfactory. It gives a beautiful beam of light, even in bright daylight, right into the wound, and no shadow is cast by it although the head of the surgeon may be between the light and the area of operation.

This result is obtained by means of a large number of mirrors disposed in an angular manner round the central light. For this light Messrs. Mann, Egerton and Co., Ltd. (5, Prince of Wales Road, Norwich, and 156, New Bond Street, London W.), have devised a special method of suspension; it has been fitted in the Norwich Hospital, and has proved very successful there. A similar fitting has been placed in the theatre of the Lowestoft and North Suffolk Hospital, and Dr. Wilson Tyson tells us that he is very pleased with the powerful illumination and with the adjustment, which allows light to be concentrated in any cavity. The suspension provides free movements—vertical, rotary to any extent, or tilted; all these movements can be effected by a light touch. The suspension fitting is not kept in stock, as the design has usually to be varied to meet the requirements of different hospitals in some particular. The light and the mode of suspension devised by Messrs. Mann, Egerton and Co. seem well worthy of the attention of surgeons.

*Apparatus for Unipolar Treatment.*

Those who read the review published on January 3rd (p. 25) of a book by Dr. Loughton Scott entitled "*The Abrams Treatment*" in *Practice: An Investigation*, will remember that the author stated that he had arranged with the Medical Supply Association to make and sell an apparatus with which can be produced the electrical changes which Dr. Scott claims effected the successful clinical result he describes. An advertisement of the apparatus will be found in our advertisement pages. It is of simple construction, and its purpose is to embody the principle of low periodic electrical pressure.

survive the operation and 44 have died since; of the remainder 15 are alive and well, after periods from five to thirteen years, and 43 are alive after shorter periods. Other researches in progress are the study of cell and tissue growth, the investigation of radium therapy in malignant disease, and a statistical inquiry into the occupational incidence of cancer.

The Middlesex Hospital has acquired, with the help of the British Empire Cancer Campaign, a further 500 mg. of radium salt, and an emanation service is to be established at the Middlesex Hospital in connexion with the radium already supplied to it.

#### CARDIO-VASCULAR RESEARCH.

Very considerable advances have been made in our knowledge of physiological and pathological conditions of the heart and circulation generally, in consequence of the installation of the "unit" system of medical and surgical teaching at University College Hospital and elsewhere. During the past year special attention has been paid to the peripheral blood circulation, and Sir Thomas Lewis, in the Cardiographic Department of University College Hospital, has concluded that the capillary pulsation is largely independent of high pulse pressure, and is due essentially to widening of the arterioles of the skin or mucous membrane in which it occurs.<sup>1</sup> With the assistance of Miss Wolf of Chicago he has made numerous thermo-electric measurements, and investigated carefully the effects of heat upon the skin. It has been shown that capillary pulsation is normal in the warmed human skin if the arterioles are present and are capable of adequate expansion, as is the case in young and healthy people. Previous statements that the capillaries of the human skin are capable of active contraction has now been independently confirmed. In a fresh investigation Sir Thomas Lewis has demonstrated that the minute vessels of the skin are capable of withstanding, by contraction, an internal pressure of 70 to 80 or more millimetres of mercury. Further inquiries have proceeded, mainly in conjunction with Dr. R. T. Grant, relative to the condition clinically termed "urticaria factitia"—a type of rapid skin oedema following skin injuries. The conclusion has been reached that skin oedema produced by mechanical, thermal, or chemical stimuli is essentially due to changes in the capillary vessel walls, and to their increased permeability. Thermal or mechanical injuries of the skin give rise to a complex reaction, which is chiefly determined by the local liberation from tissue cells of a chemical substance which leads to (a) local dilatation of the minute vessels produced by the direct action of the poison; (b) local and increased permeability of these vessels, an independent action; and (c) dilatation of the arterioles in this region and in the surrounding skin, dependent upon a local nerve reflex. When, as a result of blows, the application of heat, or of irritant substances, a small amount of poison is released, reddening of the skin occurs; when the action is more intensive oedema follows. These observations serve to link small local injuries with more widespread damage. This tissue poison, which has been shown to resemble histamine closely in its action, and which is held to be responsible for the local phenomena described when liberated in small quantities, would produce the general symptoms of shock if liberated in larger quantities, and passing into the general circulation. It is suggested that the liberation of this substance is an important factor in the normal mechanism of defence, and, thus, shock is provoked by an exaggeration of a normal physiological process. Sir Thomas Lewis, with the help of Dr. A. N. Drury, has analysed the train of causation of the numerous local and general symptoms associated with the short-circuiting of an artery with an adjacent vein, as, for example, in the case of bullet wounds. Clinical observations and conclusions in this connexion have been confirmed and amplified by the study of the experimental anastomosis of arteries and veins in dogs. Dr. F. Smith of Chicago has made an electro-cardiographic study of the events occurring when the cardiac apex is cooled in the human subject by the swallowing of much cold water. Dr. A. N. Drury has found that the vagus nerve is unable to affect the force of

cardiac contraction and the refractory period of the ventricle. He considers that the previous assertions that the vagus had such power was based on faults in the method of experiment. Dr. H. Blumgart of Boston, investigating the clinical effect of digitalis in controlling the ventricular rate in auricular fibrillation when the patient is exercised, has found that, although digitalis given in doses suitable for out-patients slows the heart rate, it does not prevent a full rise of pulse rate with exercise, although the maximal rates reached are less than in the pre-digitalis stage. Dr. R. T. Grant has completed observations of aortic lesions in infective endocarditis, and concludes that the damage to the aortic wall is entirely due to contact with vegetations seated in the valves themselves, and not to embolism, as previously it had been supposed. The nerve supply of the coronary vessels has been studied by Dr. A. N. Drury, Dr. F. Smith of Chicago, and Dr. J. J. Sumbal of Bratislava. They have found that adrenaline has a remarkable power as a coronary vaso-constrictor; that the sympathetic nerve produces a constrictor effect and the vagus a dilator effect; that the coronary nerve supplies vaso-dilator fibres to the ventricular vessels, the only peripheral effect so far ascribed to it; and that the coronary vessels are constantly dilated by pituitary extracts, acetyl-choline, and by histamine. Since pituitary extract has a constricting effect upon the arteries of the body generally, this dilatation of the coronary vessels is a striking phenomenon.

#### METABOLISM.

At the Middlesex Hospital, Dr. E. C. Dodds, studying the variations in the chloride content of the blood, has found that in the chloride interchange the most important part is taken by the blood corpuscles. Dr. H. S. Hutchison, as the result of a clinical investigation with Dr. G. Stapleton into late rickets and osteomalacia in India, has shown that these two diseases are probably due to the same pathological process, the different manifestations depending entirely upon the age of the individual affected. Until the illness which terminated in his death in March, 1924, Dr. Hutchison continued his work on infantile atrophy, and published a joint report with Dr. G. B. Fleming, on fat and protein in children. Dr. Grace Anderson, at Glasgow, has recorded an investigation into the calcium and phosphorus content of the blood in normal and in rachitic children.

#### BACTERIAL CHEMISTRY.

An important group of researches upon the chemical conditions for bacterial growth and the results of bacterial activity has been carried out during the year in the new School of Biochemistry at Cambridge under Professor Sir Frederick Hopkins. The work is done in a specially equipped department within the Sir William Dunn building.

The general problems of anaerobiosis have received special attention. Mrs. A. B. Callow has been investigating the basal metabolism of different bacteria by measuring the oxygen uptake of bacteria washed free from culture medium and suspended in a buffer solution. Miss M. Stephenson and Miss M. D. Whetham, studying the gaseous exchanges of bacteria, have been able to associate anaerobic growth with the presence of compounds which can break down anaerobically with output of energy. They have shown that anaerobic growth is made possible by the energy obtained from "coupled reactions" where the sum of the energy of the two reactions is positive. These results are of particular interest in view of the researches in progress by physiologists in connexion with the chemical changes in muscle cells. At Cambridge Dr. C. G. L. Wolf and Dr. E. K. Ridcal, investigating the behaviour of colloids with reference to the mechanism of such reactions as the Sachs-Georgi, have been able to produce antigens of almost any degree of sensitivity by using a suspensoid of a simple and easily controlled dispersion, the particles being treated with a protective agent.

#### SPIROCHAETAL DISEASES.

Dr. George Buchanan has continued his inquiries in connexion with the outbreak at East Lothian coal-pits of spirochaetal jaundice. The *Leptospira icterohaemorrhagiae* was demonstrated in several of the human cases, in rats and field-mice, and in roof drippings, but so far no evidence

<sup>1</sup> See in this connexion Sir Thomas Lewis's Sidney Ringer Lecture (BRITISH MEDICAL JOURNAL, 1924, vol. 1, p. 737).

as to the mode of infection has been obtained. Two papers on this subject have appeared recently in our columns—the first, by Dr. G. Lovell Gulland and Dr. George Buchanan, was published in the issue of February 23rd, 1924 (p. 313), and the second, by Dr. Buchanan alone, in the issue of November 29th, 1924 (p. 990). A supply of trypan-samide was received from the Rockefeller Institute at the beginning of 1924, and research is being undertaken with a view to verifying the good results obtained in New York by the use of this remedy in general paralysis of the insane. Investigation of the pathology of disseminated sclerosis is being continued along the line of experimental transference of this disease to animals, and its systematic study. It has been shown that significant nervous phenomena arise in animals inoculated from human cases of disseminated sclerosis, and in some instances the passage of the infective organism to a second animal has been successfully achieved. Spirochaetes have been found in some of these animals, but their relation to the disease is at present undetermined. The treatment of cases of disseminated sclerosis on antispirechaetal lines has resulted in some success, but it is still difficult to assess the value of the results. Dr. T. Jockes, at the Wellcome Bureau, is continuing his study of *Spirochaeta morsus muris*, the causal organism of rat-bite fever.

#### DENTAL DISEASE.

The committee for investigating the causes of dental disease has extended the scope of its inquiries; an important part of the expenditure has been borne by a grant from the Dental Board of the United Kingdom.

Dr. A. Livingston, working at King's College Hospital, has investigated the permeability of the enamel to fluids, and Mr. H. C. Malleon has shown the existence in enamel of a highly calcified prism, of an interprismatic substance, and of a prism cortex which remains after decalcification, and is presumably organic in nature. Specimens of early caries of the enamel show the presence of bacterial plaques, with deep penetrating ingrowths of micro-organisms. The mode of invasion is now being investigated. Mr. J. Howard Mummary has continued his histological study of early caries in enamel. The translucent zones of early decay, reported by him two years ago, have been re-examined with a view to obtaining further evidence as to their physiological significance. Dr. J. K. Clarke, working at St. Mary's Hospital, has isolated an organism called by him *Streptococcus mutans*, which appears to be the only organism regularly present in the early stages of caries. Artificial lesions identical with those of caries have been produced in healthy teeth placed in cultures of this organism. Two cases of infective endocarditis, due to *Streptococcus mutans*, have been studied, and it appears highly probable that the organisms gained entrance to the blood stream from carious teeth. Dr. Clarke has also begun an investigation of the etiology of pyorrhoen alveolaris. Mr. N. J. Ainsworth has completed a detailed examination of the teeth of school children in different parts of the country. A statistical analysis of his results has been made at the National Institute for Medical Research, under the direction of Dr. Matthew Young, and the results obtained are now being considered by the committee for investigating the action of dental disease, with a view to publication.

#### ANAESTHESIA.

Dr. W. E. Hume and Dr. Mona Kirkhouse, at Newcastle, have shown experimentally the value of diuretics in the treatment of cardiac oedema, but their uselessness, or even harmfulness, in cases of true renal oedema. A committee was formed early in 1924, in connexion with the Section of Anaesthetics of the Royal Society of Medicine, to study the modes of action of various anaesthetic agents, and of impurities in them. No poisonous substances have yet been discovered in samples of nitrous oxide gas which were found clinically unsatisfactory. Dimethyl ether has been suggested as a useful anaesthetic, and is being tested by Dr. K. B. Pinson of Manchester. Research is proceeding with reference to ethylene and acetylene as anaesthetic agents; we referred to their use in our issues of September 27th, 1924 (*Epitome*, para. 234), and November 15th, 1924 (*Epitome*, para. 385).

#### INDUSTRIAL MEDICINE AND FATIGUE.

An account of the results of the investigation of the relation of dust inhalation to pulmonary disease during recent years by Dr. J. S. Haldane at Oxford was embodied in a report published by Mr. H. M. Carleton. Eleven different kinds of dust to which men are exposed in mining and other industrial occupations have been experimentally studied, and evidence has been obtained that a certain degree of acclimatization can be induced by the inhalation of dust in small concentrations. It has been shown also that, as previously indicated by the experiments of Mr. Mavrogordato, whose study of miners' phthisis was reported in our issue of February 17th, 1923 (p. 299), the effects of harmful dust can be prevented to some extent by mixing it with a harmless dust. It appears that the phagocytic dust-cells are usually derived from the alveolar epithelium of the lung. Dr. T. J. Llewellyn of Nottingham has continued his research into underground illumination, with special reference to the use of tinted lamp glasses, and the results of his preliminary investigation with Professor E. L. Collis of miner's "beat-knee," "beat-hand," and "beat-elbow" have now been published by the Council. Mr. H. Lupton and Mr. C. N. H. Long, at University College, under the direction of Professor A. V. Hill, have been investigating the relation of exercise to oxygen intake; in co-operation with them Mr. K. Furusawa has shown that muscular exercise of short duration involves the oxidation only of carbohydrates. Dr. H. M. Vernon and Mr. T. Bedford have made observations in factories with regard to the influence of rest pauses on output, and Mr. S. Wyatt and Mr. A. D. Ogden have been carrying on experimental work of the same kind. We referred to the beneficial results of judicious introduction of rest pauses on March 15th, 1924 (p. 482). The causes underlying personal liability to accidents have been explored by Mr. E. Farmer, assisted by Mr. E. G. Chambers, who applied selected psychological tests to workers. So far as the investigation has proceeded there are signs that susceptibility to accident can be detected by these tests; the work is being continued at Portsmouth Dockyard.

#### STATISTICAL STUDIES.

The statistical inquiries undertaken during the year under review covered a wide field, and include independent investigations as well as co-operation with other scientific committees and individual workers. Dr. Lucy D. Cripps published a report on the application of the Air Force physical efficiency test to men and women, which was described in detail in our issue of May 17th, 1924 (p. 867). Dr. J. Brownlee has now completed his study of the various statistical methods which have been advocated in biological, physical, and chemical literature, and has been investigating the problems of human fertility with a view to throwing light on the statistical facts relating to birth control. A large volume of data for the study of environmental factors, including records of 10,000 children, has now been obtained by house visitations on a large scale in Glasgow, Dundee, Edinburgh, and various agricultural and mining areas in Scotland; this material is now being examined statistically. Sir St. Clair Thomson has published a statistical report of ten years' experience of tuberculosis of the larynx at King Edward VII Sanatorium at Midhurst, and Dr. P. S. H. Hartley, Dr. R. C. Wingfield, and Dr. J. H. R. Thompson have produced a similar report and an inquiry into the after-histories of patients treated in Frimley Sanatorium between 1905 and 1914; this was described in our issue of August 9th, 1924 (p. 244). Statistical research on the same lines is proceeding at Midhurst. Other inquiries of this kind made include investigations of the relation of weather to bronchitis and pneumonia in children under 5; the effect of social conditions upon the growth and development of young children; and the influence of fog upon respiratory disease, with especial reference to the years prior to 1890. The occurrence of epidemics of influenza in more recent years has introduced a complicating factor into this problem.

### ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

THE Memorandum of the evidence to be given on behalf of the British Medical Association before the Royal Commission on Lunacy and Mental Disorder is published in the SUPPLEMENT this week. The committee appointed by the Association to prepare the evidence has kept in mind the principle that the interests of the patient as a sick person should be the first consideration. Subject to this principle, due weight was given to the claims of the public as a whole for protection against any improper restriction of individual liberty on the one hand, and against the risks which attach to the inefficient control of persons of unsound mind on the other, and likewise to the claims of the medical profession for adequate safeguards in carrying out the difficult and responsible duties placed in the hands of its individual members.

General approval will, we anticipate, probably be given to the recommendations made for amendment of the terminology used in the Lunacy Acts. The term "lunatic" should certainly be discarded, and one substituted which will still be satisfactory from the point of view of law and administration. The Committee recognizes that psychiatric classification, subdivision, and definition, so far from being helpful, would be a hindrance when considering mental disorder in its legal aspects. Thus a psycho-neurotic may need legal control, while a psychotic may sometimes be quite properly treated in an uncertified clinic. From a legal standpoint a social rather than a medical classification of mental disorder is required, and, bearing this fact in mind, the Committee has suggested that disorders of the mind, excluding mental deficiency, should be divided into "mental ailments," in which measures of control are not necessary, and "mental unsoundness," in which such measures are desirable. The latter term is intended to cover those cases now included under the term "lunatic" as employed in the Lunacy Acts, or, as we hope they will in the future be called, the "Mental Disorders Acts." The need for definition of these two categories is particularly emphasized when the provisions of Section 315 of the Lunacy Act, 1890, are considered. Here, unless the phrase "a person of unsound mind" were limited to those persons who, by reason of mental disorder, may properly be taken charge of and detained for care and treatment, the section would forbid the reception and treatment in nursing homes of patients who, though mentally disordered, do not require detention or control.

The treatment of the "mentally ailing" does not usually give rise to serious difficulties under the existing law, however, as such patients do not need control; the facilities for dealing with these cases away from home are certainly far from adequate at present, but this deficiency would no doubt be automatically remedied when an amended law permits of a greater variety of places in which mental abnormality as a whole can be treated. For the "mentally unsound" there is a serious need for more flexibility in arrange-

ments, and every medical practitioner must have found himself in difficulties, owing to the rigidity of the present law, in dealing with cases included within this category. Recognizing the reluctance of patients and their friends to apply for a reception order by a judicial authority, the Committee has endeavoured to suggest less formal arrangements for suitable cases. Experience has shown that many patients needing control, being aware of their instability, are willing to deprive themselves of their liberty; and since the principle of voluntary boarders was adopted an increasing number of patients have availed themselves of this mode of entry into those institutions in which it is permitted. The suggestion that the voluntary principle should be extended to non-volitional types, such as the confused, depressed, and stuporose, has much to commend it. This will actually be only an extension of the same privilege to certain "insane" cases—the privilege of being treated without certification, as is granted to a patient (say) with typhoid delirium; after all, this condition is a psychosis as much as any other morbid mental state in which the causation is more obscure.

As regards those patients who are unwilling to be treated, and for whom control is necessary, it is recommended that a Provisional Order should be allowed in suitable types, as it is felt that by this less formal procedure time for observation will be made available, and thereby the necessity for full certification will be avoided in case of recovery. There is little doubt that if legal sanction were given to these various suggestions the possibilities for the treatment of mental disorder suitable to the needs of the individual case would be greatly increased. As the Memorandum shows, in addition to the existing types of accommodation for patients suffering from mental disorder, treatment would be developed in non-registered hospitals or adjuncts to hospitals, voluntary or Poor Law; in clinics or homes established by local authorities; in homes established on a charitable or semi-charitable foundation; and in recognized homes on a purely private basis for several patients. Apart from any such additional provision, the Committee is of the opinion that all the existing facilities for treatment should be continued. The Memorandum states that the Association is satisfied, having elicited the opinion of practitioners in various parts of the country, that there exists a desire in the community generally that it should be permissible to treat many patients otherwise than in public institutions; should the existing veto on the setting up of new licensed houses or the extension of existing licensed houses result in the diminution or inadequacy of this provision, it may be necessary to repeal this veto or to provide extended facilities for the treatment of patients in small numbers in private hands under proper safeguards.

It is most desirable that the apprehensions of the medical profession in regard to certification should be set at rest. Apart from the fact that no one is anxious to be involved in expensive litigious proceedings, and least of all a busy practitioner, a reluctance to certify on the part of the doctor may result in the very delay in treatment which is likely to diminish the prospects of recovery. The Committee points out that it has become customary to speak of "certification" as being the fact which deprives the patient of his freedom, whereas, of course, the formal authority is in all cases the Order, and this is not made by the certifying doctor but by the judicial authority, or, in the case of the urgency order, by a relative. While it is desired to guard against the elevation of the medical

certificate to a position of authority which it does not possess, there is no wish on the part of the Association to underestimate the great importance of the certificate as evidence. Indeed, it is desired to insist upon its being given very definitely the status of evidence; and therefore that the protection which witnesses in courts of law are entitled to receive shall be extended to the practitioner who signs a certificate under the Lunacy Acts.

The Committee points out that, while the avoidance of an undeserved stigma, by allowing less formal arrangements, is much to be desired, it must be borne in mind that the associations springing from any arrangements will depend in the long run upon the actual facts and usage, and not upon any verbal description or sympathetic intention. Escape from stigma is practically impossible when the stigma is justified by facts. Giving a disorder a different name or treating it in a different type of institution certainly will not alter its character or lessen its serious import. Under existing conditions, however, a stigma tends to be applied indiscriminately to all certified patients; it is thus not based upon the biological facts in any particular case, but upon the patient's social classification. In advocating new methods of dealing with mental disorder the medical profession has no desire to minimize the serious nature of the problem created by its increasing incidence in civilized communities; on the contrary, it is hoped that by bringing the whole problem into the open and by educating the public to face realities, so that knowledge may replace fear, the possibilities, not only of the cure of mental disorder, but of its prevention also, will be greatly increased.

### SYMPATHETIC RAMISECTOMY.

For some time it has been known that skeletal muscle is connected with the sympathetic nervous system as well as with the cerebro-spinal, and the functional significance of the former innervation has been widely discussed in recent years. De Boer and Langelaan formed the opinion that muscle tonus was dependent upon the sympathetic nerve supply, but their views have been hotly contested by subsequent writers, particularly on account of the uncertain effects upon decerebrate rigidity which have followed experiments on the sympathetic. Recently the late Professor J. I. Hunter,<sup>1</sup> whose early death we had the grief to record in our issue of December 20th (p. 1181), and Dr. N. D. Royle<sup>2</sup> of Sydney have very thoroughly reinvestigated this important problem. In a most interesting series of experiments they discovered evidence that the sympathetic has an undoubted influence upon one aspect of muscular tone. After simple excision of the sympathetic fibres to one limb a "depression in reflex excitability and an inability to maintain the posture of the limb" were observed. Excision of the sympathetic supply in cases of transverse section of the cord led to a marked alteration in posture and diminution in the amplitude of the deep reflexes on the side where the sympathetic influence had been removed. Undoubtedly the most startling results were those obtained upon decerebrate rigidity. In a group of experiments upon goats, in which the sympathetic fibres to the left hind limb were excised and the animals allowed to recover from this before decerebration was performed, it was discovered that either

decerebrate rigidity did not appear in the left hind limb (in the case in which seventy-three days elapsed before decerebration), or that there was a pronounced difference in the amount of rigidity on the two sides. It seems probable that the striking result attained in this group of experiments was due to the introduction of an interval between the two operations. From an analysis of their experiments Hunter and Royle concluded that removal of the sympathetic innervation of voluntary muscle abolishes the "plastic tonus" of Sherrington; they advanced strong evidence that the somatic reflex arcs determine the posture of a limb, and that the position assumed is maintained through the sympathetic influence. The discovery made, largely through the researches of Kulchitsky, that the sympathetic fibres to striated muscle do not reach the same muscle fibres as the lower motor neurones, lends some support to the conception of muscle tonus advanced so lucidly by Hunter and Royle, since it appears probable that muscle fibres innervated by the sympathetic are concerned with "plastic tone," and those supplied by somatic nerves with what Langelaan has described as "contractile tone."

These brilliant researches are likely to have not only a far-reaching influence upon knowledge of the sympathetic nervous system and upon neurology in general, but also, if wisely applied, to prove of great value in the treatment of certain spastic conditions. Following on their experimental work, Hunter and Royle have respectively devised and practised in a large number of patients the operation of "sympathetic ramisection," in which the grey rami communicantes to the nerve roots distributed to one or more of the limbs are divided or avulsed. After the removal of the efferent part of the reflex arc necessary for the maintenance of plastic tone marked diminution of spasticity ensues in patients in whom there is an excess of this form of tone, but such an operation will have no effect upon contractile tonus. Furthermore, such a procedure does not reduce the voluntary control; on the contrary, it releases function which has been prevented by the spasticity, and this must be developed by a carefully planned course of re-education and training commencing as soon as possible after the operation.

The operation elaborated by Hunter and Royle has now been performed by several surgeons in this country and in America, and anyone who has had an opportunity of studying the striking results which occur in suitable cases is compelled to admit that a surgical measure for the treatment of spasticity has now been suggested promising to have far-reaching results. This form of treatment offers an obvious and very significant advantage over any other yet practised, in that it does not involve any sacrifice of voluntary function in the procedure necessary to reduce the spasticity. This appears to be an important point, and should be emphasized when the operation—which is clearly an intricate and difficult one—is compared adversely with some of the simpler procedures advocated at the present time. As the pioneers in this field of surgery have demonstrated, care must be taken in the selection of patients for treatment by sympathetic ramisection. If all cases of spasticity are treated indiscriminately in this way there is a risk that this most promising therapeutic measure may fall into disrepute. Already slight criticism has been heard because the operation has not benefited patients suffering from lesions which render them quite unsuitable for this form of treatment. The principal indication for the operation is an excess of plastic tone,

<sup>1</sup> John I. Hunter: *The Postural Influence of the Sympathetic Nervous System. Brain*, Part 3, vol. xlvii, 1924, pp. 261-274.

<sup>2</sup> Norman D. Royle: *The Problem of Treatment of Spastic Paralysis: an Experimental and Clinical Study. Ibid.*, pp. 275-322.

and it is obviously only to be recommended in the case of patients possessing at least a moderate degree of cortical control. As was to be anticipated from this, it has been found that the best results are to be expected in patients suffering from cortical lesions. The operation is designed to remove the sympathetic influence, and through it plastic tonus, from the spastic skeletal muscles, and it is important that the surgical interference should, as far as practicable, be limited to this—that is, division of the grey rami communicantes passing to the nerve roots distributed to the affected muscles. Already in some cases surgeons have divided the sympathetic cord or in other ways disturbed the distribution of the sympathetic to abdominal viscera, with unfortunate results. It has been hinted that in the future the fundamental principles enunciated by Hunter and Royle may be applied to the treatment of some abdominal conditions, but if we are to make real progress in this direction further experimental research is required; in the meantime resection must be limited as closely as possible to the sympathetic fibres passing to the limbs. We hope shortly to publish a full discussion of this most important subject.

### VERONAL AND BARBITURIC DERIVATIVES.

The enterprise of the organic chemist has supplied the medical profession during the last fifty years with a whole armoury of new synthetic drugs, many of which are of the highest value, but this rapid advance has introduced its own special problems. The general tendency is to produce drugs of ever-increasing potency, and the more potent a drug is for good the more dangerous it is when misused.

The potent galenicals in general use consist of a limited number of old-established drugs, and the medical profession is well acquainted with their advantages and disadvantages. There is, however, no limit to the possible number of synthetic drugs, and, in point of fact, new remedies appear every month. The drug houses owning the proprietary rights can be trusted to spread a knowledge of the advantages of any new synthetic remedy, but unfortunately there is no equally efficient method of spreading the knowledge of its disadvantages, and in actual practice it may take years for the medical profession to get adequate knowledge of the possible dangers of any new drug. The evils of this state of affairs are well illustrated by the case of the veronal group of hypnotics.

Veronal was discovered in 1902, and was soon found to be more potent as a hypnotic than any drug previously synthesized. It also, in no long time, became evident that it was a highly dangerous drug when taken in large doses. It is true that recovery has occurred after a single dose of 100 grains, but, on the other hand, death has followed doses as low as 15 grains. Reports in the medical press and from the coroners' courts have acquainted the medical profession with the possible dangers of veronal, but unfortunately the value of this knowledge is lessened by the fact that a crowd of veronal derivatives have been put on the market under names that fail to suggest any connexion with the original and best known drug. Veronal is di-ethyl barbituric acid, and has received the pharmacopoeial name of barbitone, but it is also sold under the names malonal and hypnogen. Barbituric compounds or derivatives are sold under the following names: medinal, propanal, luminal, dial, valisan, allonal, chineonal, and somnucetin. There may be others of which we have not yet heard. Speaking

quite generally, the veronal derivatives are, on the whole, more powerful, and therefore more potentially dangerous, than veronal itself, but the confused nomenclature makes it very possible that a doctor who has found veronal unsatisfactory may turn to an alternative drug, and only learn by bitter experience that it is practically the same thing under a new name.

We cannot see that any public interest is served by a system which allows a potent drug to be sold and advertised to the medical profession under a dozen different names. The procedure with each new veronal derivative is nearly always the same: the drug is given a fancy name, often no mention is made of its relation to veronal, and it is stated to be a potent hypnotic, harmless even in overdoses and incapable of habit formation. These statements are broadcasted to the medical profession, and it takes years to get the real truth established; by that time perhaps a dozen new drugs have appeared. In particular the commonly made statement that some brand-new hypnotic is incapable of habit formation is really an insult to the intelligence of the medical profession, for no safe judgement on this point can possibly be made until a drug has been in fairly widespread use for some years.

Veronal (barbitone) and the barbituric derivatives are potent drugs, peculiarly dangerous in overdoses, and capable of producing habit; hypnotics, moreover, are a class of drugs with which there is a special liability to indiscriminate self-drugging. We are therefore glad to learn that the Home Secretary is considering the advisability of restricting the sale of this group of drugs to the general public and, as already announced, is consulting the British Medical Association on the subject. Such legislation would have the incidental advantage of making clear to the medical profession which proprietary drugs actually belong to this particular group.

### MR. RUTHERFORD MORISON.

MR. RUTHERFORD MORISON of Newcastle is shortly to receive from those who know him best a tribute to the esteem and affection in which he is held. A letter on another page shows that a short time ago a meeting called by the Newcastle-on-Tyne Division of the British Medical Association appointed a committee to consider how best to recognize Professor Morison's services to the medical profession. The committee decided to present Mr. Morison with his portrait in oils, and to devote the balance of the amount subscribed to the formation of a medical library fund, the establishment of a scholarship or fellowship in research, or such similar object as Mr. Morison may approve. The first list of subscriptions, published as a postscript to the letter, shows that the replies will be very ready and from a wide field. We have no doubt that many who have not been Mr. Morison's pupils and not intimately associated with him in his surgical work, but who admire his qualities as a man and a surgeon, will wish to share in the tribute now to be paid. Mr. Morison graduated M.B. Edin. in 1875, became F.R.C.S. Edin. in 1879, and F.R.C.S. Eng. in 1890. He first entered general practice at Hartlepool, but his high competence, both as a surgeon and a pathologist, led to his appointment to the surgical staff of the Newcastle Royal Infirmary; his connexion with it was maintained when he retired from the active staff in 1913 by his appointment to be consulting surgeon. In the following year his old house-surgeons placed a medallion profile portrait on the wall of the operating theatre which he used when surgeon to the institution. His services to the School of Medicine in Newcastle-on-Tyne were so great that he may be said to

have made it. He was pre-eminent as a teacher, and allowed nothing to interfere with his duties in that capacity. One of his colleagues writes to us: "As a general surgeon he is without rival; he is a specialist in most things. He is a general stimulus wherever he goes, his usual plan being to make a controversial statement to start a discussion." With students his popularity was unbounded, and all looked forward to his visits to the Royal Victoria Infirmary, for everyone recognized his integrity, his optimism, and his energy. His generosity to those in distress is unbounded, particularly to his brother practitioners. Once, when this same colleague was attending a clinic at the Bellevue Hospital, New York, Dr. Stewart introduced him to the class as an old pupil of Mr. Morison's, and told the members that "there are two surgeons in the world who write their own observations, and only of their own observations—one is Rutherford Morison, the other is W. J. Mayo." In addition to being surgeon to the Infirmary he was professor of surgery in the University of Durham, and is now emeritus professor. Though he had retired from hospital practice, as we have said, in 1913, when the war broke out he resumed duty as honorary surgeon to the Royal Victoria Infirmary, and was also surgeon to the Northumberland War Hospital. It was during this period he devised the solid antiseptic "bipp," of which we had occasion to say only the other day that it was such an antiseptic paste as Lister sought; as is well known, it came into very general use in war surgery. It is one of the war innovations which have survived and will survive. Mr. Morison has not written very much, but has contributed from time to time a number of papers to our columns, all marked by originality and practical acumen, and all informed by his profound knowledge of pathology and immense experience. With the title *Surgical Contributions* he published in 1916 in two volumes a collection of his monographs, and his *Introduction to Surgery* is too well known to call for more than mention. He is always quick to recognize ability and energy. One of his late colleagues tells us that one of his characteristics was rapid decision and confidence in his decision; confidence if once given was rarely withdrawn. "Any man who took an intelligent interest in surgery or pathology could count himself fortunate beyond his fellows if he made the acquaintance of Rutherford Morison; this innumerable students and practitioners have found. Nothing was a trouble to him if it came in the course of surgery, and it was only necessary to mention to him an interesting pathological condition or some unusual surgical case for him to take an early opportunity of going with his colleague to see it. Morison's industry and thoroughness were splendid in themselves, but when added to something like an instinctive power of diagnosis they made the wonderful surgeon he is. The secret of Morison's influence as a teacher lay in his painstaking forethought about everything he had to do and to his worship of duty." In yet another direction Mr. Morison's services to the body of general practitioners in the North of England have been invaluable. In the late nineties, when the colliery doctors began a long (and ultimately successful) campaign for the improvement of their remuneration, he threw himself heart and soul into the movement. He went about using his great influence with the miners and their leaders, and gave up a great deal of time to the movement. He also subscribed handsomely, and never forgot he had been a general practitioner. One of the most important results of Mr. Morison's work then was to set an example to the consultants of the district which has been generally followed. In no part of the country can the general practitioners depend with more certainty on the active support of the consultants than in the North of England, and this can be distinctly traced to Mr. Morison's influence.

### THE MUSEUM OF AUSTRALIAN ZOOLOGY.

THE announcement that the Commonwealth Government has passed an Act to establish a Museum of Australian Zoology will be hailed with the greatest possible pleasure by men of science throughout the world. The title is to be noted: it is a museum of Australian zoology, and not an Australian museum of zoology. Macaulay's schoolboy did not know, but probably most schoolboys to-day do, that evolution in the island continent went along different lines from those of the rest of the world. Apparently the wrong road was taken, and it seems to be agreed that the whole indigenous fauna of Australia is only too likely to follow Tasmanian man to extinction. It would seem that the process cannot be arrested by the best wisdom of Australian statesmen, but whether this pessimistic view be wholly true or not there is clearly an obligation on Australia to preserve a full series of specimens. This is what the Australian Government and Parliament have, under the inspiration of Dr. Colin Mackenzie, decided to do. Comparative anatomy is one of the foundation sciences of medicine; the Australian fauna illuminates it in many places, and its study, though zealously prosecuted for more than one generation, still calls aloud for the work of many another. The nucleus of the national Museum of Australian Zoology is a collection—undoubtedly the greatest in the world dealing with the Australian fauna—which the Federal Parliament of Australia accepted from Dr. Colin Mackenzie last August. It is now established in Melbourne, but will eventually be transferred to the new Commonwealth capital at Canberra, which will then become the world's greatest centre for the study of the Australian fauna. Dr. Colin Mackenzie has been appointed its first director, with the title of professor of comparative anatomy, and he may be trusted to make every effort to render the collection complete. With the cordial approval of the Prime Minister and the Department of Home Territories of the Federal Government, he is now issuing an appeal all over Australia for specimens, drawings, and documents. The scheme seems to command unanimous approval in Australia, and when the bill was before Parliament it was supported by three medical men—Dr. Earle Page (Federal Treasurer), Sir Neville Howse, V.C., K.C.B., and Dr. Moloney, members of different parties in the House. The action of Mr. Stanley Bruce, the Prime Minister of the Commonwealth, in obtaining the Mackenzie collection for Australia may justly be compared with Pitt's far-seeing act in securing the Hunterian Museum for the British nation, where it has formed the nucleus of the great collection of the Royal College of Surgeons of England. The establishment of the Museum of Australian Zoology is a recognition that comparative anatomy is not merely an academic matter, but one of primary importance to medical science and to biology generally.

### PROGRESSIVE LENTICULAR DEGENERATION.

SINCE the appearance in 1912 of the original paper by S. A. K. Wilson describing the disease which he named "progressive lenticular degeneration," more than seventy cases of this condition have been reported, and F. M. R. Walshe has now contributed to a recent number of *Medical Science* a review of present knowledge about this disease. The characteristic symptom of progressive lenticular degeneration is the development of tremor and rigidity of the muscles, which is usually associated with dysarthria, dysphagia, spasmodic weeping and laughing, and a slight degree of dementia. Occurring in youth and early adult life, and varying in duration from a few weeks to several years, it is always fatal. The muscular tremor resembles that of paralysis agitans, but is not invariably present;

usually, however, it is the initial symptom, and remains prominent throughout the course of the disease. In a small number of cases defective articulation was the first symptom. Occasional silent laughter or weeping attacks occur, passing in slow waves across the patient's face, which is otherwise fixed and like a mask; saliva trickles from the angles of the open mouth. Until advancing rigidity renders the trunk and the limbs immobile no true paralysis occurs, and the tendon-jerks and abdominal and plantar reflexes remain normal in uncomplicated cases. The original lesions described by Wilson include bilateral degeneration and softening of the putamen and caudate nucleus, together with a profound degree of hepatic cirrhosis, which, however, does not give rise to biliary symptoms. A zone of greenish haze at the periphery of the cornea has been described in some cases, and is possibly present, though undetected, in others. German writers have described a "pseudo-sclerosis," which appears to be only an alternative and undesirable name for this condition; H. C. Hall has suggested as a better title "hepatolenticular degeneration." Walshe considers that the disease can no longer be regarded as a system disease of the corpus striatum; although there are indications that the liver is the seat of the primary pathological process, the nature of the pathogenic agent is as yet unknown. Wilson suggested that a toxin elaborated in the liver, and possessing a selective action upon the lenticular nucleus, was responsible for the cerebral lesion. Evidence in favour of this suggestion has been advanced by Barnes, who recently described a family of eight children; four showed signs of hepatic disease, and in two of these there was evidence of progressive lenticular degeneration. Although chronic manganese poisoning is known to be associated with a clinical picture resembling that of paralysis agitans, and with the occurrence of asymptomatic biliary cirrhosis, yet Walshe considers that the doctrine of the selective action of poison upon various components of the central nervous system is not gaining ground. Such obscure and variable factors as lymphogenous intoxications, and the existence of histo-chemical peculiarities in the nerve cells of the basal ganglia, have also to be taken into account.

#### INTESTINAL STASIS.

On November 22nd, 1924, we drew attention in a leading article to some experiments by Drs. Alvarez and Freeland on the passage of food through the bowel, the main teaching of which was that food residues are mixed up thoroughly in the caecum, so that the residue of any one meal will be represented in the faeces in decreasing proportions over a period of many subsequent days. The novel features of these experiments were the technique used and the conclusion that any unabsorbable remnant may take a much longer time to pass from stomach to anus than we have been accustomed to allow. Dr. J. C. Watt comments on this work in a letter which we publish to-day (p. 138). He has also sent us a copy of the pamphlet to which he refers, and, since this is a more detailed account of the thesis advanced in his letter, by shelling out the kernel of this treatise we shall enable our readers to weigh its substance and more justly to appraise Dr. Watt's notions. This pamphlet, entitled *A Study of Intestinal Stasis*,<sup>1</sup> is not a reprint of an article printed in a medical journal, as it appears to be at first sight, for the author tells us ingenuously that he has failed to get it accepted, and that one "editorial scrutineer" condemned it so heartily as "greatly to encourage" the author in publishing it. In addition to courage, the author must therefore be credited with a sense of humour. Nor is it a pamphlet available to the curious for a modest sixpence or a shilling. It bears

no reference to any vulgar coin, but, with splendid brevity, on the inner side of the cover carries the inscription, "First published April, 1922. Manufactured in Great Britain." Turning to the contents we find an invective and very sensible exposition of the doctrines of intestinal stasis on similar lines to those of Sir Arbuthnot Lane. Dr. Watt's first point is that constipation is essentially a pathological delay of the faecal stream which may be said to commence when the interval between evacuations is sufficiently prolonged to permit decomposition of faeces by bacteria to take place in the colon. We are driven to the conclusion that the only unconstipated ones among us are tiny infants who have not yet had the bad habit of only a single daily evacuation thrust upon them. The author passes on to consider the consequences of this intestinal stasis, and we find, as might be expected, that the list of maladies for which this prevalent sluggishness of the bowel is to blame is long and portentous. However, it is by no means exhaustive of the evils to which flesh is heir, and we can recollect many far less moderate incriminations of the colon. The remedy recommended for pathological dilatation of the caecum is the operation of amputation of the caecum, "not excision," as a footnote says, "but simple amputation immediately below the ileo-caecal valve." A case is described in which this operation was performed, and the patient appears to have benefited thereby. Dr. Watt takes great pains to explain in detail the mechanical principle on which the secondary stages of stasis are dependent. He likens the alimentary system to a river or a canal with a series of locks, the lock gates being the cardiac orifice of the stomach, the pylorus, the ileo-caecal junction, and the pelvi-rectal junction. Since the cause of alimentary stasis must be distal to the most distal stagnant part of the tubular system, it follows that the area referred to as the pelvi-rectal junction is likely to be the danger spot of the human frame. To this conclusion Dr. Watt leads his readers, and congratulates himself on the fact that he has reached the same conclusion as O'Beirne of Dublin, who in the year 1833 published a book entitled *New Views of the Process of Defecation*. The last pages of the pamphlet describe a new operation designed to relieve the obstruction at the pelvi-rectal junction. It is suggested that the last part of the pelvic colon should be stitched to the upper part of the rectum, and then through a transverse slit in the pelvic colon the intervening crest formed by the adjacent walls of the colon and rectum should be crushed with forceps. Finally, after withdrawing the crusher, the crushed septum should be divided with scissors and the "window" in the colon closed. The stages of this operation are made clearer by a diagram, and a feeling of responsibility compels us to warn surgeons not to embark on this operation trusting to the meagre description we have found space to give, but first to study Dr. Watt's opinions in the original. We presume that the pamphlet can be obtained from the printers; if not, no doubt from the author. It has been placed in the Library of the British Medical Association.

#### POSTURE AND REST IN MUSCULAR WORK.

REPORT No. 29 of the Industrial Fatigue Research Board contains two papers—one by E. M. Bedale, M.A., entitled "A comparison of the energy expenditure of a woman carrying loads in eight different positions," the other by Dr. H. M. Vernon on "The influence of rest pauses and changes in posture on the capacity for muscular work." These papers have a theoretical interest for physiologists, and a practical interest, not only for employers, but for manual workers. But we doubt very much whether the last named class would be disposed to take the pains

<sup>1</sup> London: John. Bale, Sons and Danielsson, Ltd.

<sup>1</sup> London: H.M. Stationery Office, or through any bookseller. 1924.  
2s. 6d. net.

necessary to understand these reports, or have been prepared by their previous reading and experience to do so; the whole thing would be like a foreign language. Perhaps some propaganda machinery exists for conveying the information to them; if not it should be called into being. There is nothing unexpected in either of the reports. The majority of sensible people, if asked the questions the experimenters have so laboriously studied, would have arrived at much the same conclusions. In saying this we do not wish to belittle the work, for it is obviously of considerable value to convert an opinion into a demonstrable fact, and doubtless there exist many employers who will pay more attention to a weighty report of the Industrial Fatigue Research Board than to mere general impressions. We do not suggest that they are wrong. The chief points of practical importance seem to be that if it is anyone's duty to carry a fairly heavy load, then the easiest way (the one demanding least physiological "cost," in the technical language) is to divide it into two equal parts and sling it from a shoulder-yoke. The other practical point is that if there is an opportunity for a rest pause in the course of industrial work the posture should be changed, even if the pause lasts only a minute. Thereby the circulation through fatigued muscles is promoted and fatigue diminished. Changes of posture during work may be even more refreshing than rest pauses. These are not the only opinions substantiated by this inquiry; they seem, however, to be those of widest interest. Something requires to be said about the form in which this type of report is presented to the public. The majority of such reports follow a stereotyped plan; they rarely make any attempt to be interesting, although the subjects with which they deal are often such as closely concern everyday life; there is seldom, if ever, any promise that the information they contain will be translated into practical benefit. We do not mean to imply that this is the fault of the authors of the reports; it may very well be that the department or the Stationery Office has a bed procrustean in breadth as well as length, but the net result is to make the conscientious reader wonder how many others will have patience to continue from cover to cover. We make the suggestion that editors of such reports should first explain in plain language why the investigations described were undertaken and the benefits which the new knowledge offers; this section should be written in an interesting way so as to encourage all sorts of people to read it. The remainder of the report, in smaller print, perhaps, should give an account of the details of the scientific experiments for the sake of the smaller number of readers who can only be convinced by the scientific demonstration, or who, having specialized knowledge, find entertainment therein.

#### THE EFFECT OF LEAD ON RED BLOOD CELLS.

THE interpretation of the change in the red blood cells, which is termed "punctate basophilia" or "stippling," has given rise to considerable controversy. It has been attributed to the occurrence of artefacts (due to the staining reagents used), to degeneration, and to regeneration of the cell protoplasm. Punctate basophilia has also been regarded as pathognomonic of lead poisoning. Dr. Cecil Price-Jones, in a review of the subject,<sup>1</sup> insists that it is not specific, but is common to all forms of anaemia in which the products of red cell destruction are retained in the body. The anaemia of lead poisoning, he says, is usually slight, and the red cells are little diminished in numbers, though there may be some alteration in shape and size. An increase in diameter has been observed by Malassez from the normal  $7.7\frac{1}{2}$   $\mu$  to  $9.9\frac{1}{2}$   $\mu$ . Leucocytosis is not often present, and the white

cell picture is lymphoid in type, showing a relative and absolute increase in the number of large mononuclear cells up to 16 to 24 per cent. Basophilic stippling of the red cells is sometimes observed, but not so frequently as was formerly supposed. This basophilia is often seen in diseases associated with anaemia, especially when there is retention in the circulation of the products of destruction of red cells, as in malaria, pernicious anaemia, and the anaemias secondary to toxic infections. In post-haemorrhagic cases it is less common, unless the haemorrhage has been severe; but in gastric haemorrhage, where the blood is digested and the products of blood-cell destruction are absorbed into the system, stippled cells are often found in large numbers. Basophilia rarely occurs in chlorosis, and never in aplastic anaemia. Dr. Price-Jones maintains that it is only, and always, associated with accelerated or exaggerated activity of the bone marrow. The researches of Pappenheim have thrown considerable light on the nature of these basophilic granules, and there appears to be abundant evidence that they have no connexion with the nucleus or with nuclear derivatives. Considering the morphology and staining reaction of the lymphoid parent cell, Pappenheim regards polychromasia and punctate basophilia as remains of the spongioplastic reticular ground substance, the varying sizes and positions of the granules and the degree of basophilia depending on the mesh and density of the spongioplastic network and of the position of its nodal points. McCord, Minister, and Rehm believe that in all cases of lead poisoning an excess of "basophilic substance" is present in certain of the red cells, and is distributed uniformly throughout the cell. They regard this basophilia as an indication of the precocious introduction of red cells into the general circulation. They have devised a method of estimating the amount of basophilic substance which aggregates the minute invisible basophilic particles into coarser masses which can be enumerated. They find that 66 per cent. of the blood examinations of healthy persons show a few of these aggregations, and that they are present in great numbers in a variety of diseased conditions, especially those involving anaemia. It is their experience that the majority of workers in lead quickly develop a higher basophilic aggregation count than is found in healthy persons; and they consider that if at successive examinations this count is found to be increasing, the workers should be submitted to lead eliminating or lead controlling treatment, even if no clinical manifestations of lead poisoning are present. Dr. Price-Jones lays stress on some new observations of Aub, Reznikoff, and Smith; they consider that the physio-chemical reactions of lead salts of red blood cells are chiefly surface phenomena resulting in increased cell fragility. They found that the red cell resistance to haemolysis was increased by treatment with lead chloride, and that the specific gravity of the cell was raised. Dr. Price-Jones concludes that the changes produced by lead depend upon its union with the inorganic phosphate of the cell; this is mainly a surface phenomenon; the very insoluble lead phosphate is precipitated in the cell membrane, changing its colloidal properties. Alternatively, the free acid formed when a lead salt unites with the phosphate may change the physio-chemical state of the colloids of the cell surface; such altered cells haemolyse less rapidly in diminishing concentrations of Ringer's solution; the cell surface shrinks and the cells break up more rapidly than do healthy cells. They lose their power of agglutination, and have a surface which is less sticky; they become hard, less elastic, and far more brittle than normal cells. These damaged cells break up rapidly in the capillaries, and the anaemia commonly seen in lead poisoning develops. This anaemia, which is rarely extreme, is associated with the appearance of basophilic granules in some of the red cells.

<sup>1</sup> *Medical Science*, December, 1924, p. 147.

## ACUITY OF HEARING.

Dr. H. J. BANKS-DAVIS chose acuity of hearing as the subject of his presidential address to the West London Medico-Chirurgical Society.<sup>1</sup> He related some observations of his own on the hearing of cats and of fishes. The hearing of cats was extraordinarily acute, so that the highest sound produced by Galton's whistles—42,000 double vibrations a second—was painfully audible to them. Two Manx cats in his possession during the war used to be aware of impending air raids many minutes before the warning signal was given. Fish, in Dr. Banks-Davis's opinion, heard sounds communicated to them by water through water, but not by air through water. Firing a gun in a direction parallel to the water's surface produced no noticeable effect on fishes; but they became disturbed at once when a stone was allowed to fall on the gravel of the river bed, or when the ground of the bank was stamped on, or a railway train passed. Bait "heavily flopped" into the water attracted trout from a tunnel in which neither scent nor sight could have guided them. An abbot at a monastery used to attract the carp for feeding by ringing a bell, until it was found that the footsteps of the procession had the same effect without the bell. Dr. Banks-Davis recalled the fact that many albino animals are congenitally deaf, as in the case of many, if not all, white cats with blue eyes, and many white bull-terriers, white rabbits, white mice, white elephants, and even some white horses. The acute hearing of deer is overshadowed by their abnormal sense of smell; but may not the close proximity of the camera to some of the African deer, as shown in films, cause some doubt whether the hearing of deer is really acute? Insects often "hear" by their antennae. Snakes have no properly formed auditory apparatus, but appreciate the vibrations of sounds and respond to them. In comparing human beings with animals, it was found that oto-sclerosis, which is common in women, is very common in cats. Many animals besides cats can hear sounds too high to be heard by man. Dogs are pained by high musical notes which may give pleasure to the human ear. Deafness such as that of boilermakers and artillerymen can be produced in animals; and if the noise is loud enough or sufficiently prolonged degeneration of the organ of Corti may occur. Dr. Banks-Davis's only hint of treatment for defective hearing was an expression of surprise that, while people readily resort to glasses when vision is defective, they resent artificial aids to hearing. It would be interesting to know in what proportion of cases of deafness benefit is obtained from artificial aids at all comparable to that obtained from glasses.

## THE VECTOR OF KALA-AZAR.

It has been known since 1903 that Indian kala-azar was caused by the protozoon *Leishmania donovani*. The parasite is normally intracellular, and is the resting stage of a flagellate. It consists of a small oval organism with two chromatinic bodies, giving it a very characteristic appearance. The forms are not common in the blood, although they do occur. In culture the parasites develop typical flagellate forms, which have been placed by some authors in the genus *Herpetomonas*—a simple flagellate with a free anterior flagellum and no undulating membrane such as occurs in the trypanosomes. These forms have been frequently found in the gut of insects. This fact has made it probable that the disease is transmitted by some biting insect, although so far it has not been possible definitely to implicate any form. Patton believed that it was transmitted by the bed-bug; but the more recent work of Knowles, Napier, and Smith<sup>2</sup> suggests that the sand-fly may be the intermediate host. If the present preliminary

account is confirmed it will be one of the most important discoveries of recent years in tropical medicine. It has been observed that the greatest number of new cases of kala-azar were reported during cold weather, so that probably the infection was contracted in the course of a few months before November; it was thought, therefore, that the most favourable time for investigation would be during that period. It was found that in Calcutta an endemic area existed, and that in the northern part of the city the disease fails to spread or establish itself. It was also known previously that the distribution of the sand-fly, *Phlebotomus argentipes*, in India appeared to coincide with that of kala-azar, and these insects were more numerous in the endemic than in the free area. It was ascertained that of the three species of sand-fly present in the city, *P. argentipes* was especially prevalent during October and November. Some significant experiments were conducted with this species; in eleven experiments in which 56 flies were fed on seven kala-azar patients, 25 were found to contain herpetomonad protozoa in the gut; while in over 800 controls not fed, and 46 fed on healthy persons, no herpetomonads were found. The authors conclude that *Leishmania donovani* passes into its flagellate form in the gut of *P. argentipes*. No experiments, however, have been performed to see whether the reverse is also the case, and the authors are most careful not to draw unwarranted or speculative conclusions as to transmission until the further work now in progress is completed.

## MEDICAL SOCIETY OF LONDON.

The syllabus for the second half of the 152nd session of the Medical Society of London has just been issued. Three general discussions have been arranged. The first, on February 8th, on the treatment of lymphadenoma, will be opened by Sir Thomas Horder, followed by Drs. Herbert French, N. S. Finzi, and Robert Knox. The second, on March 9th, on the fundus oculi in general medicine, will be opened by Mr. Ernest Clarke, followed by Mr. R. Foster Moore and Dr. James Collier. The third, on March 23rd, on oxaluria, will be opened by Mr. L. Batho Rawling, followed by Sir William Willeox. At the meeting on January 26th Dr. Castellani will read a paper on parenteric fevers; and on February 23rd Sir G. Lenthal Cheate will read a paper on the early stages of pathological hyperplasia in the breast, with special reference to cysts and their danger. The meetings of February 16th, March 4th, and March 16th are appropriated to the Lettsomian Lectures, by Sir Bernard Spilsbury, on wounds and other injuries. The concluding meeting of the session will be held on May 11th, when the annual oration will be delivered by Sir William Hale-White on the medical career of John Keats; a conversazione will follow.

The Right Hon. Sir Clifford Allbutt, K.C.B., Regius Professor of Physic in the University of Cambridge, has accepted the invitation of the Council of the Royal Society of Medicine to deliver the David Lloyd Roberts Lecture during the autumn session of this year.

We announced last week that the two conferences at Geneva on the Hague Opium Convention of 1912, which adjourned before Christmas, would resume work on January 12th. A formal meeting was held on that day, when the president announced that owing to the accident to the Marquess of Salisbury, the British first delegate, the proceedings would be postponed until Monday next, January 19th, when Viscount Cecil of Chelwood, who has been appointed in the place of Lord Salisbury, will be in attendance.

## THE LONDON RADIUM INSTITUTE.

When the London Radium Institute was opened in August, 1911; it was described in our issue of August 5th, 1911 (p. 302), as "complete"; but in this field of medical science, even more than in other medical research, it has been found

that the horizon has considerably enlarged with the passage of years. Gratifying advances in the technique and the applicability of radium therapy have necessitated expansion of the work of the Institute, and so the size of the present building is now nearly three times that of the original. Since 1911, 10,200 patients have been treated within its walls, and 4,500 others in their own homes or elsewhere, emanation applicators being prepared and distributed to hospitals and general practitioners throughout the United Kingdom. The total number of treatments to date is 103,000, no less than 60 per cent. of them gratuitous. This great act of public service, initiated by King Edward VII, and rendered possible by the generosity of the Earl of Iveagh and Sir Ernest Cassel, has been conducted on the lines of a charitable trust, no appeal being made for public support.

When the work of the Institute began external radiation was the only method of treatment. This was followed by tentative insertion of radium into such channels as the urethra, vagina, and oesophagus, with a view to dealing more effectively with new

Similar procedures are practicable in other localities, as, for example, in malignant disease of the bladder and of the uterus.

For patients able to pay for treatment in the Institute seven private bedrooms have been available for the last two years, but hitherto it was impossible to treat necessitous patients otherwise than as out-patients, or in their own homes, "surgery of access" being impracticable. It was therefore felt that an increase in the size of the Institute was urgently needed in order to accommodate these patients; and, as we recorded last week (p. 86), two new wards have been opened on the second floor, providing four cubicles for women and three for men. These wards form part of a self-contained unit with a small operating theatre for the performance of minor operations. Having a southern aspect, they receive all the sunshine available; and their architectural features are in keeping with the rest of the building. A well fitted theatre in the older part of the Institute is fully adequate for any of the more elaborate operations which may be necessary.

The Institute possesses what are probably the best equipped laboratories of their kind in the world; any form of apparatus required is constructed in its engineering workshop on the third floor, or the carpenter's shop in the basement. Tubes can be designed suitable in size and shape for any contingency. The chemical laboratories have been improved and are likewise complete in every respect. On the ground floor, which is devoted to diagnosis, the medical superintendent's consulting room, x-ray room, and a gynaecological examination room, are so arranged as to permit the simultaneous examination of three patients. On the first floor are situated the treatment rooms—seven in number—an operating theatre, and the seven bedrooms for private patients. The Institute at the present

time possesses as much as 6 grams of radium bromide. No operable cases of malignant disease except rodent ulcer are treated by radium at the Institute, unless the patients have declined operation, and every effort is made to

RADIUM INSTITUTE: FRONTAGE TO RIDING HOUSE STREET.

MAIN OPERATING THEATRE.

carcinoma of the larynx the radium rays could only be directed very imperfectly and their dosage regulated. The present procedure comprises tracheotomy, subhyoid pharyngotomy, and the direct needling of the growth.

persuade patients who have previously refused operation to give their consent. Radium treatment, however, although thus limited almost wholly to inoperable cases, has achieved very striking results; some of the patients who were first treated in 1911 are still living, the progress of their disease having been arrested. Radium is being employed in the treatment of a large number of diseases other than malignant, including keloids, naevi, tuberculous glands, lupus, rheumatoid arthritis, uterine fibroids, metrorrhagia, skin diseases, exophthalmic goitre, Hodgkin's disease, leucocythaemias, and spring catarrh. Great care is taken to select cases suitable for radium treatment; patients are only received through medical practitioners, and it is obligatory that a medical form, giving details of the exact nature and extent of the disease, shall be supplied before admission. The new wards are primarily intended for patients who are able to pay the cost of their food while in the Institute, the treatment being given free. No really necessitous patient, however, is refused admission if it is likely that radium treatment will be beneficial.

The present chairman of the committee is Sir Anthony Bowlby, who succeeded the late Sir Malcolm Morris. The late Sir Frederick Treves was chairman from 1909 to 1923. A considerable amount of research work—clinical, pathological, and physico-chemical—is in progress. This extension of the work of the Institute marks a distinct advance in the progress of radium therapy there. Beyond the great boon conferred by providing treatment for the poorer members of the community, the increased facilities for research work should open the way to still greater additions to our knowledge of one of the most potent of therapeutic measures.

## France.

[FROM OUR OWN CORRESPONDENT.]

### THE LATE PROFESSOR BERGONIÉ.

THE whole country has been deeply moved by the death of Professor Bergonié. He adds one more name to the long martyrology of the pioneers in x-ray work. The value of his work and the example of fortitude he leaves behind him mark out Bergonié as one of those heroes of whom the international medical fraternity must be proud. Death broke him down piece by piece, but his soul remained indomitable. Bergonié was professor of physics at the University of Bordeaux. He undertook the investigation of electro-radiology, and he determined to set this new branch of studies on a scientific basis. During the war he organized the whole system of hospitals for the treatment of wounded men by physiotherapy. He understood quickly enough that these methods were insufficient and that a thorough cure meant re-education and readaptation to work. To him were due the agricultural training centres. His last years were devoted to the fight against cancer. He knew his time was short when three years ago he had to submit to amputation of his right arm. With restless activity he created in Bordeaux the first anticancer regional centre, and pursued his mission in Lyons, Strasbourg, Montpellier, and Toulouse, with headquarters in Paris. He took the chair "for the last time" (as he said) in Paris three months ago. He then gave his opinion on the way the work should be carried on and expressed his wishes as regards his successor. A generous gift of one of his admirers allowed a new cancer hospital to be erected in Bordeaux. Bergonié was carried out of his home for the last time for the laying of the first stone; and there were gathered all his co-workers and colleagues from every French university. The Government had bestowed upon him the highest dignity in the Legion of Honour. The rule being that the insignia should be handed over to the new dignitary by one of the same rank in the order, it was Marshal Petain himself who made Bergonié Grand Cross of the Legion of Honour. As *becomes a fighter wounded on the field, full military honours were rendered when Professor Bergonié was carried home. He died a few days later. By his will he made a substantial gift to the anticancer organization, and expressed his desire*

that a post-mortem examination of his body should be made so as to control his clinical observations on himself and bring some light on the question of x-ray burns.

### STATE HEALTH INSURANCE.

The general meeting of the Union of Medical Syndicates has just been held in Paris. The principal subject to be discussed was, of course, the question of State health insurances. The very existence of practitioners being at stake, it is not surprising to notice the unanimity of our medical deputies in defending the interests of the profession at large. It is to be remembered that the new legislation has been accepted by the Chamber and will before long come before the Senate. The law is to be presented by Dr. Chauveau, a senator and a medical man, to whom befalls the difficult task of contenting both the *chère* and the *chou*! Hitherto practically all the social laws relating to medicine were carried under the understanding that the doctor was a philanthropist only too pleased to give his time and to get, after many years, an official *lettre de félicitations*, or maybe to insert into his buttonhole some blue or red, or red, white, and blue ribbon. The actual conditions of life, and the rate of taxation in particular, have put our services towards the community on a quite different basis. This is precisely what has not yet been understood by the promoters of an insurance system. We dimly understand that we shall have rough seas to weather, and a unique front of resistance has been formed by the union. The position is very much like that the British Medical Association had to face some years ago. How much some of us would wish to see that our present union should turn into a broad French Medical Association. At any rate, we have expressed our opinion in three very simple rules: (1) the patient shall have the right of choosing his own doctor; (2) the sacred rule of professional secrecy shall not be infringed; (3) fees to be per visit, with no so-called "inclusivo" agreements. No doubt I shall have to refer to this question in these columns more than once.

### PRIZES OF THE ACADEMY OF MEDICINE.

At the annual meeting of the Academy of Medicine the secretary, Dr. Souques, pointed out that eleven prizes out of fifty-five were not awarded for the simple reason that there were no competitors. These prizes consist of sums of money, former legacies, most of them memorials. The depreciation of our currency has made the value of these premiums rather negligible, the amount being insufficient in many cases to meet the secretarial expenses of the candidate. In some instances, too, the subjects proposed to investigators sound rather obsolete. For instance, there is a prize promised to the happy one who will provoke "thyroid tumour" by administration of substances extracted from water. Well, well, as my young friend said, there are years when you do not feel like working.

G. MONOD.

## Victoria.

[FROM OUR SPECIAL CORRESPONDENT.]

### SIR GEORGE SYME.

SIR GEORGE SYME, President of the last Australasian Medical Congress, resigned active practice in June, 1924. As a mark of the high esteem in which he has long been held by the medical profession in Victoria he was recently presented with his portrait, painted in oils by Mr. John Longstaff. The President of the Victorian Branch of the British Medical Association, Dr. J. W. Dunbar Hooper, made the presentation in the presence of a large gathering of medical colleagues and friends of Sir George, and he asked Lady Syme to accept a replica of the portrait. The Rev. Dr. Sugden, Master of Queen's College, Dr. Zivar of the Melbourne Hospital, and Dr. Murray Morton of St. Vincent's Hospital supported Dr. Hooper, and all expressed their appreciation of Sir George and Lady Syme in brief but admirably chosen words. Sir George, who was obviously touched by the graceful compliment, replied on behalf of Lady Syme and himself.

## THE NEW BUILDING OF THE VICTORIAN BRANCH.

The accommodation of the Victorian Branch of the British Medical Association in Melbourne has long been out of date, antiquated, and wholly insufficient for its purpose. The urgent need of new premises has been insisted upon by many past presidents and councils, and, with the war a thing of the past, it has at last been found possible to take action. After a long survey of possible sites it has been decided to rebuild on the present site. The old one-storied building has been demolished, and a new two-storied structure is now in course of erection. Dr. J. W. Dunbar Hooper laid the foundation stone of the new building immediately after the presentation to Sir George Syme. The new building, when completed, will provide adequate accommodation for the library, the Council and its committees, and the monthly scientific meetings of the Branch. Provision has also been made for the addition of a third story when required. After the new premises have been completed the war memorial of the Branch, temporarily housed in the anatomy department of the University, will be transferred to its proper quarters, and will there form a permanent and beautiful tribute to the memory of those members of the Branch who laid down their lives for King and country.

## THE MEDICAL SCHOOL OF THE UNIVERSITY.

The year 1924 has seen many changes in the medical school of the University. The magnificent department of anatomy, opened some fifteen months ago by the late Sir William Macewen during his visit on behalf of the British Medical Association, has been in permanent occupation for the whole of the last academic year, and has given the greatest satisfaction to all concerned. The evacuation of the old anatomy department has enabled the medical school library to be transferred to larger and more suitable quarters, and has also given much needed relief to the departments of biochemistry and pathology.

## DEAN OF THE FACULTY OF MEDICINE.

The serious and, it is feared, permanent breakdown in health of the professor of pathology and dean of the Faculty of Medicine, Sir Harry Allen, has been universally regretted, the more so on account of his long and honourable association with the medical school of the University. As it no longer appears to be possible to hope for his return to duty, the University Council has been compelled to take steps to appoint a new professor of pathology. The Faculty of Medicine has elected Professor R. J. A. Berry dean of the faculty.

## THE HOSPITAL SITE.

It has long been felt that the complete topographical separation of the medical school of the University from the clinical hospitals is not only anomalous, but detrimental to medical education, research, and the profession generally. An ideal site for hospital and medical school, known locally as the market site, of about fifteen acres, exists immediately west of the University, but the short-lived Labour Government of Victoria allocated this valuable site to the State Education Department, and did so without making any provision for Melbourne's most pressing necessity—additional hospital accommodation. In the new Government a medical man is now Chief Secretary of State, and his action in the matter is being awaited with considerable interest.

## England and Wales.

## WELSH NATIONAL MEDICAL SCHOOL.

We have referred on several previous occasions to the proposal to separate the Welsh National Medical School in Cardiff from the South Wales and Monmouthshire University College. A crisis appears to be developing now, and Cardiff is threatening to withdraw from the University of Wales and establish a university of its own. Since the establishment of the University of Wales in 1893, the University has retained some degree of central control over matters of finance and policy relating to its constituent colleges at Cardiff, Aberystwyth, and Bangor, and now at

Swansea. Special departments for agriculture exist at Aberystwyth and Bangor; Aberystwyth also has a law department, Swansea a school of metallurgy, and Cardiff its medical school. The recommendation of the Royal Commission of 1918, over which Lord Haldane presided, and to which we referred in our issue of July 19th, 1924 (p. 126), was based on a serious reason for separation. The college at Cardiff had applied to the Treasury for a substantial increase in its annual grant, and the Treasury, apprehending that such a grant would be taken as a precedent by other colleges, declared that it could not make a grant to a medical school belonging to a single college, though it might do so in the case of a national medical school. This ground for separation was shortly afterwards cut away when the Government decided to make additional grants to the universities and colleges of England and Wales on a new and purely arithmetical principle—according to them in the form of "pound for pound" equivalents to such additional local grants as the several institutions might obtain. The grants to the University of Wales and its colleges were pooled, and the delicate task of dividing them among particular institutions was transferred to a local body. The question of a special grant from the Treasury to the Cardiff medical school therefore lapsed, and Sir Isambard Owen, late senior deputy chancellor of the University of Wales, in a statement published in the *Western Mail* of January 9th, takes the view that the commissioners' recommendation on the subject may be considered to have lapsed simultaneously. At the present moment the proposed new charter of the college at Cardiff is being considered by the Privy Council; this charter would provide for the medical school remaining a constituent part of the college. Dr. J. G. Adams (Vice-Chancellor of Liverpool University) contributed to the *Western Mail* of January 8th an article setting out the case for opposing the suggestion to make the Welsh National School of Medicine an institution independent of the University College at Cardiff, and cites the precedents of such medical schools as those of Manchester, Liverpool, and Leeds in England, the twelve medical schools of London, the Montreal School of Medicine in Canada, and the medical schools of Sydney, Melbourne, and Brisbane in Australia. Sir Isambard Owen contends that the college at Cardiff originally established the medical school and provided for its needs. He believes that the more closely the management of any school of medicine is connected with the immediate locality in which it is situated the better its general progress, since a school of medicine is dependent for its very existence upon its relations with local authorities. The financial side of the question has a serious bearing on the issue, for should Cardiff eventually secede from the federal university, out of the £54,000 yielded by a penny rate from the whole of Wales in support of the University, over £33,000 is contributed by Glamorgan, Monmouthshire, Brecon, and the county boroughs of Cardiff, Newport, and Merthyr. One story is good until another is told. As we have on previous occasions pointed out, there is a strong body of opinion in favour of making the Welsh Medical School a national medical school with its headquarters at Cardiff, but directly related to the University of Wales.

## Ireland.

## PROFESSOR PURSER'S GIFT.

PROFESSOR JOHN MALLET PURSER has made a gift of £10,000 to be administered for the benefit of the School of Physic and the Schools of Experimental and Natural Science of the University of Dublin by a committee consisting of the heads of three of the scientific departments of the college. The Board of Trinity College, in gratefully accepting his most generous donation, has expressed to Professor Purser its desire that he should associate himself with the committee in the administration of his gift, and Professor Purser has consented. His connexion with the teaching staff of Trinity College dates from 1874, when he was appointed King's Professor of the Institutes of

Medicine (Physiology and Histology) by the Royal College of Physicians. He held this professorship until his resignation in 1902. Probably no man exercised a greater influence over the minds of generations of students in the school during these twenty-eight years. He not only was responsible for the teaching of physiology, but was, it is believed, the first man in Ireland to give formal lectures and conduct practical classes, not only in histology but also in modern pathology. During the years that he held the King's professorship he acted as physician to Sir Patrick Dun's Hospital. In 1917 Dr. Purser was nominated by the University Council, and appointed by the Board of Trinity College, to the Regius Professorship of Medicine, a position he still holds. This appointment gave the greatest pleasure and satisfaction to his many former pupils. His numerous friends and admirers, not only in Dublin but all over the world, hope he will continue to hold this high position for many years to come, and preside over the School of Physic in their old university, to whose services he has devoted his life.

## Scotland.

### THE WESTERN INFIRMARY, GLASGOW.

We have already mentioned that the Western Infirmary, Glasgow, is celebrating its jubilee, and then gave some account of the progress which has been made in the fifty years. The Board of Management has now issued, with illustrations, a short history of the institution, written by Mr. William Power. The Infirmary and the University buildings, closely adjoining at Gilmorehill, were erected simultaneously. Glasgow required additional hospital accommodation, and the situation was most convenient alike for the population rapidly extending along Clydeside and for the staffing of the new institution in its relation to the medical school. An important contribution to the building fund was, in fact, made from University resources. Early differences of opinion, perhaps jealousies, are wisely passed over in the history with no more than a hint, and are of no moment to-day. How rapidly an institution for healing develops and expands in modern times is strikingly illustrated by the recorded facts and figures noted in our previous article (p. 45). The wards have been quadrupled in number, and the indoor patients are five times as many as half a century ago. Then the medical staff consisted only of physicians and surgeons; now there are also gynaecologists, surgeons for the ear, throat, and nose, dermatologists, anaesthetists, and medical electricians. The first visiting physicians were Sir William T. Gairdner, Sir T. McCall Anderson, and Dr. James Finlayson. The first visiting surgeons were Sir G. H. B. MacLeod, Dr. George Buchanan, and Dr. Alexander Patterson. Not very long ago in these columns<sup>1</sup> a notice appeared of an admirable thumbnail sketch of these six men by the late Dr. Walker Donnic, published, alas, only posthumously by his widow, and then only for private circulation; but the work can be consulted in the library of the British Medical Association, and doubtless in other medical libraries; old students who have not chanced to see it will find that it recalls, both good-naturedly and incisively, the traits of the teachers at whose feet they sat so many years ago. Mr. Power's little history goes on to tell the story of the growth of the Infirmary, of its pathological department under Dr. Joseph Coats, its museum and laboratories, its x-ray department, kitchens and laundries, Samaritan Society, Lady Hozier Home, operating theatres, massage department, training school for nurses, and all the other activities carried on under the chairmanship of Colonel J. A. Roxburgh, D.L., with the aid of its medical superintendent, Colonel D. J. Mackintosh, C.B., and its matron, Miss H. Gregory Smith, R.R.C. The endowment fund now exceeds £250,000, and the capital or supplementary fund is about £60,000. Last year the maintenance expenditure, including that of the Lady Hozier Home, was fully £80,000, with the result, unfortunately not uncommon in such matters, that the

ordinary subscriptions, supplemented by the interest on endowment and capital funds, left a balance of £14,000 to be drawn from extraordinary receipts which ought to have gone wholly to increase the interest-bearing capital. Notwithstanding this, supporters of the voluntary principle of hospital maintenance may look with a large degree of satisfaction on the financial position of the Western Infirmary of Glasgow.

### EDINBURGH ROYAL INFIRMARY: SAMARITAN SOCIETY.

The annual meeting of the Edinburgh Royal Infirmary Samaritan Society was held on December 9th, 1924. The Hon. H. Dalrymple, president, in moving the adoption of the annual report, said that the society had for forty-six years carried on most excellent work in connexion with the various hospitals in Edinburgh. Among other things, it had recently helped some of those in hospital with arrears of rent. During the past year 335 new cases had been assisted in various ways, and the almoner and her assistant had paid 1,442 visits. The expenditure in the clothing department was £274, which was more than in the previous year, but this was due to the increasing number of requests made for clothing by patients in very poor circumstances. The subscriptions received during the year had amounted to £256. A motion was proposed by the Rev. Dr. Black to urge upon the public the need that existed for giving increased support both by annual subscriptions and by contributions of clothing. He said that the society discharged a very useful function in giving the extra bit of care which nobody else did, because the mere use of the Infirmary was not enough when the breadwinner of a family that was just managing to carry on was cut down. Councillor Harvey, in seconding this motion, referred to the splendid complementary work that the society was doing in the City Hospital by bridging the gulf that lay between sickness and complete restoration to health. A vote of thanks was proposed to the committee of management and other office-bearers by Mr. George Chene, F.R.C.S.

## NEEDS OF SCOTTISH HOSPITALS.

### OPENING OF PUBLIC INQUIRY.

AN inquiry at the instance of the Scottish Board of Health into "the extent and nature of the inadequacy of the present hospital and ancillary services in Scotland" was opened on January 6th, in the Board of Health Offices at Edinburgh. The Committee, which was appointed last summer, is under the chairmanship of the Hon. Lord Mackenzie, and consists of Mr. J. Addy, Edinburgh; Mr. John Birnie, Inverness; Dr. R. C. Buist, M.R.C.P. Ed., Dundee; Dr. A. K. Chalmers, F.R.F.P.S. Glas., medical officer of health for Glasgow; Mr. John S. Doeg, Aberdeen; Dr. J. R. Drever, Edinburgh, Secretary of the Scottish Branch of the British Medical Association; Dr. D. J. Mackintosh, C.B., M.V.O., LL.D., Glasgow; Mr. Niven McNicoll, Secretary of the Committee; Mr. Russell Paton, Edinburgh Royal Infirmary; Mr. James Robertson, Dumfries; Mrs. Elizabeth Shirley, Dumfries; Sir Norman Walker, F.R.C.P. Ed., LL.D.; and Mr. Joseph Wung, Bellshill, Glasgow, chairman of the Scottish Labour Housing Association. A further remit to the Committee was to make recommendations for the development and maintenance of these services to meet the needs of the community, and it covers in addition to voluntary hospitals the services of public health and Poor Law hospitals.

The chairman in opening the inquiry said that the first task was to make a survey of the hospitals in Scotland, and this to a large extent had been carried out during the past six months. It had been established that there was inadequacy, and the great problem which confronted the community was to be solved by a careful, comprehensive, and detailed study of the situation rather than by starting with theories and endeavouring to make these theories fit the facts. He had studied the pamphlet entitled *The Labour Movement and the Hospital Crisis*, and also the hospital policy of the British Medical Association, as well as the report by Lord Cavo's Committee and the report of Viscount Knutsford's address on April 28th, 1924. Those who were acquainted with the subject would recognize that

<sup>1</sup> March 1st, 1924, p. 334.

these were the protagonists of the various schools of thought. It would have to be considered whether the task before the nation was so enormous that no voluntary organization could tackle it alone, or whether the State alone could deal with it without voluntary aid. A full and complete health service was needed, one which was available for all who required it; and the efficiency of that service would depend upon the establishment of intimate co-operation and harmonious relationship between the various kinds of hospitals. They wanted to know how far the problem was one of actual shortage of something which was really needed for the welfare of the community, and how far it was simply a problem of reorganizing and grading existing accommodation.

The first witness examined by the Committee was Dr. A. E. Maynard, F.R.F.P.S., Governor of the Victoria Infirmary, Glasgow, who said that, speaking only for the city of Glasgow, he considered that the existing institutions were totally inadequate as regarded the number of beds required in the three large general infirmaries. The inadequacy might be measured by the following considerations: (1) partly by the long waiting lists; (2) partly by the fact that general practitioners were unable to gain admission for patients whom they recommended; (3) more especially by the staff, who were unable to admit patients whom they knew for various reasons should not be kept waiting for treatment; and (4) partly by the effect which delay in admission had on employers and insurance associations. Payments had to be made where immediate treatment of a comparatively slightly disabling complaint would admit of the employee returning to his work and benefiting by again earning full wages. Instances of this nature were innumerable. This witness also said that there was pressing need for a class of patients, who, by reason of their social position or their limited means, were not suitable for admission to purely charitable institutions, but who, at the same time, could not pay the larger fees required for entrance to private nursing homes. Provision could quite well be made in their voluntary institutions for this class on condition that expenses were covered by the patients' own contributions. Provision was also needed for the observation of disease at its earliest manifestations. He was of opinion that the present needs of the community could best be met by the adoption of two measures: (1) the building of convalescent or auxiliary hospitals at convenient distances from the parent institutions; and (2) the building of cottage hospitals in towns where the distance was too great for patients to be conveniently transported to the cities.

The next witness was Professor G. L. Gulland, C.M.G., of Edinburgh University, who said that, as regarded male wards in Edinburgh, the physicians found they could keep within a reasonable distance of their waiting lists, but that, as regarded female cases, the waiting lists were often six months in arrear, and the difficulty particularly applied to chronic cases. He thought there was need in the Edinburgh district for further auxiliary hospitals, but that it was desirable that most medical cases should pass through the general hospitals in the first place, that was to say until a diagnosis was made. He thought that the hospitals were too solidly built and that the ideal for a hospital was some temporary structure designed to last only thirty years. With regard to paying patients, he did not think that it would be suitable to treat paying and non-paying patients in the same wards. He thought, however, that the principle of a voluntary hospital consisted only in voluntary and independent management, and was not necessarily accompanied by gratuitous treatment in all the wards. In Edinburgh a departure from the gratuitous principle was about to be made in the matter of the x-ray department, and it was admitted that that was the thin end of the wedge. The Royal Infirmary of Edinburgh had also departed from the gratuitous position to a considerable extent by taking subscriptions from employees of all kinds, and he thought that opinion had changed and was still changing with regard to the admission of paying patients in voluntary hospitals. He thought that so long as independent management was preserved, the public would continue to subscribe and he thought there would be no disinclination by any class of persons to come into the Infirmary. The demand for hospital treatment was certain to increase on account of the rising standard of medical and surgical diagnosis, and this was also affected by the fact that many of the houses now built did not provide sufficient room for treating sick persons at home.

Sir George Beaton, K.C.B., K.B.E., of Glasgow, stated that he did not think that the fairly well-to-do middle classes were adequately provided for in nursing homes, and he suggested the establishment of paying hospitals or of paying beds in existing hospitals. He thought that the lower middle classes, including artisans, manual workers, and the poor, were not sufficiently provided for at present, and in order to ensure adequate hospital treatment there should be co-ordination of all the hospitals—voluntary, municipal, and Poor Law. He did not think the voluntary hospitals should be linked up with the Poor Law hospitals but with the health authority institutions. Each hospital should be absolutely independent of State or any other control in the management of the hospital. As to the cause that had brought about the deficiency in accommodation in voluntary hospitals, he held that the voluntary hospitals had not confined their work to the care of the necessitous sick poor for whom they had been established, but were now meeting the needs of the lower middle classes, artisans, and others. There had been a great influx of this class of patient owing to the disappearance of the prejudice

that formerly existed against entering a hospital, partly due to recognition of the advantages offered by the hospitals and partly due to the difficulty of obtaining home nursing. He believed that the organization best suited for the voluntary hospitals was the establishment of a Scottish Central Hospital Committee, which should have power to regulate the building of new hospitals and the extension of existing institutions, and also to raise a central fund for the benefit of all the voluntary hospitals in Scotland. He proceeded to elaborate this scheme, according to which Scotland would be divided into four districts, each having central hospitals with auxiliary recovery hospitals round them to allow of "evacuation." Each district would have clearing houses under a commissioner for the allocation of beds in the recovery hospitals. As regarded finance, all patients admitted to the voluntary hospitals should be under a certain income limit and should meet their individual maintenance charges. He thought that this system of maintenance by the patients—either personally or through the aid of insurance—would foster thrift, and it would preserve the voluntary character of the hospitals, which at the present day was very desirable. He did not think that nationalization of hospitals would be so efficient as the present system, and it would be more expensive.

Sir David Wallace, K.B.E., C.M.G., Vice-President of the Royal College of Surgeons, Edinburgh, said that during his period of connexion with the Royal Infirmary of Edinburgh there had been a great evolution in hospital accommodation and treatment, in regard, for example, to the number of branches of hospital work. The general voluntary hospital had thus a larger function to fulfil, and he anticipated that this would entail larger extra expenditure in the future. He believed that the voluntary principle was best for patients, for medical men, and for the community as a whole; and he thought congestion in these hospitals might be relieved by the introduction of auxiliary hospitals, which had worked well in the war, and which might be used in connexion with civilian hospitals. This principle had been introduced in Edinburgh in the Astley Ainslie Institution, where patients were sent from the Royal Infirmary. A great number of surgical cases merely occupied beds, and after operation patients really required only nursing and general attention, which could quite well be carried out in auxiliary hospitals, thus freeing beds in central hospitals. He thought that all hospital buildings should be of the simplest possible description, and that the principle of a monument to the architect in hospital construction should now cease. Many country houses were coming into the market and could readily be converted for use as auxiliary hospitals. With regard to Poor Law hospitals, he believed that if these institutions got the reputation of having competent men doing the work people would go to them without any thought of there being any stigma attached, and it might be best that the Board of Health should take them over.

#### Maternity Needs.

Professor B. P. Watson, F.R.C.S., Professor of Midwifery in the University of Edinburgh, expressed the opinion that in the Edinburgh district maternity hospital conditions were at present very inadequate, and it was impossible to keep patients in hospital longer than nine or ten days after delivery. He also thought that private patients were inadequately provided for in private nursing homes. He suggested that private wards should be attached to the large public hospitals, so that all the facilities of these hospitals should be available for the better class of patient. He referred to his experience in Toronto, Canada, where in the university teaching hospital, having a total accommodation of about 600 beds, 150 were intended for private patients, who not only met the charges for their hospital maintenance but paid their doctors' fees. These patients were accommodated in a separate building in the hospital grounds. From the running of the private wards there was a considerable surplus which went toward the maintenance of the public part of the hospital. Every patient, however, paid for maintenance, a principle which was general throughout Canada, and, if they could not pay individually, their municipality or district paid for them. This principle was followed throughout the United States also, and it worked exceedingly well. He thought that it ought to succeed in Scotland, and, if a private pavilion could be built in the grounds of the Royal Infirmary at Edinburgh it would be a tremendous benefit to the community. In answer to a question, the witness said that in the Edinburgh district the minimum for a new maternity hospital would be 200 beds.

Professor T. K. Monro, F.R.F.P.S., Professor of Medicine in Glasgow University, said that there were 1,200 persons on the waiting list of the Glasgow Royal Infirmary, and he thought that a temporary extension might be enough to clear off these cases. He did not think that the housing question had much influence upon the congestion in regard to hospitals. With regard to the type of case on the waiting list, there were seven to fourteen times as many surgical cases as medical cases waiting for admission. He believed in the maintenance of the voluntary system, and thought that if there were a State service there would be a great increase in the cost of running expenses.

Professor Archibald Young, F.R.F.P.S., Professor of Surgery in the University of Glasgow, said that the inadequacy of the present hospital provision was beyond dispute. As a hospital surgeon, he saw it particularly in the continual demand for admission, which it was almost impossible to meet. The question of inadequacy was somewhat complicated by the fact that a small cottage hospital could suffice for a large population in the country districts because many cases of all kinds sought, or were sent, for treatment to the large centres, where, they thought, they could get better treatment. The public was becoming more and more alive to the fact that in the modern hospital all kinds of treatment might be got on a scale that even the best equipped nursing home could not surpass, and the hospital patient of to-day, speaking generally, had a higher

level of facilities for diagnosis, as well as for treatment, than his supposed better class brother or sister. He thought that further hospital provision should take the form of extension of existing hospitals, partly in the form of provision of auxiliary hospitals or convalescent homes linked with the central hospital. He did not believe that any great advantage would be gained by an attempt at further co-operation between the various larger hospitals, nor did he think that the inadequacy problem would be materially affected thereby. The voluntary hospital was entitled to expect contributions from National Health Insurance funds, and the National Health Insurance scheme must continue these. The provision and maintenance of hospitals especially for insured persons was quite out of the question. He saw no essential objection to the acceptance by a voluntary hospital of funds derived from State grants. The witness thought that there might be co-operation between voluntary hospitals and Poor Law hospitals by linking up one voluntary hospital with one Poor Law hospital. He thought that the independent control of voluntary hospitals should be continued. On the question of payment by patients for their maintenance, the witness saw no objection to the principle, and, although he did not think that paying and non-paying patients should be treated in the same ward, he thought it might be economical to have them under the same roof and saw no objection to this.

The committee adjourned until January 13th. We intend to publish a report of its further proceedings in our next issue.

## Correspondence.

### RUTHERFORD MORISON TESTIMONIAL.

SM.—A largely attended meeting, representative of all branches of the medical profession, was held in Newcastle-on-Tyne on December 16th last, as a result of the subjoined resolution passed by the Newcastle-on-Tyne Division of the British Medical Association:

"That a meeting of the medical profession in the North of England be called as soon as possible to consider how best to recognize Professor Rutherford Morison's services to the medical profession."

At this meeting it was unanimously decided to issue an appeal to the profession for subscriptions—(a) to present Mr. Morison with his portrait in oils; (b) after defraying the cost of the portrait, to devote the balance to the formation of a Medical Library Fund, or the establishment of a Scholarship or a Fellowship in Research, or such other similar object as Mr. Morison approves. It is hoped to raise a sum of at least £2,000.

A General Committee was formed to further the object, together with an Executive Committee, who are:

Angus, Professor H. Brunton  
(Chairman), Newcastle.  
Anderson, Dr. J., Blyth.  
Anderson, Dr. P. V., Bishop  
Auckland.  
Arkle, Dr. J. S., Newcastle.  
Bolam, Dr. R. A., Newcastle.  
Bunting, Dr. T. L., Newcastle.  
Charles, Dr. J., Consett.  
Densham, Dr. H. B., Stock-  
head.  
Dickie, Dr. H., Morpeth.  
Dickie, Mr. W. S., Middles-  
brough.  
Dix, Dr. R. H., Sunderland.  
Don, Dr. J., Newcastle.  
Fairclough, Dr. W., Hexham.  
Hare, Dr. F. F. T., Durham.

Harland, Dr. G. R., S. Shields.  
Hudson, Dr. J., Newcastle.  
Mackenzie, Dr. W., Gosforth.  
Martin, Mr. A. M., Newcastle.  
Murray, Dr. Farquhar, New-  
castle.  
Ogden, Dr. O. W., Newcastle.  
Pearson, Dr. H. C., Darlington.  
Purves, Dr. Scott, Alnwick.  
Smallwood, Dr. R. H., Gates-  
head.  
Turner, Mr. G. Grey, New-  
castle.  
Walkinshaw - Osselton, Dr.  
Eleanor, Newcastle.  
Williamson, Dr. J. B., North  
Shields.

Attached is a list of the subscriptions which have been received or promised to date. Subscriptions may be sent to the honorary secretary and treasurer, Mr. R. J. Willan, F.R.C.S., 6, Kensington Terrace, Newcastle-on-Tyne.—We are, etc.,

H. BRUNTON ANGUS,  
Chairman.  
R. J. WILLAN,  
Honorary Secretary.

Newcastle-on-Tyne, Jan. 8th.

#### FIRST SUBSCRIPTION LIST.

£22 10s.—Mr. Hamilton Drummond (Newcastle), Mr. G. G. Turner (Newcastle), Mr. R. J. Willan (Newcastle).  
£25.—Professor H. Brunton Angus (Newcastle), Mr. A. M. Martin (Newcastle), Dr. J. W. Smith (Ryton).  
£21.—Dr. R. A. Bolam (Newcastle), Dr. James Don (Newcastle), Dr. James Hudson (Newcastle), Dr. D. F. Todd (Sunderland).  
£15 15s.—Dr. J. S. McCracken (Newcastle).  
£10 10s.—Dr. Baigent (Northallerton), Dr. R. H. Dix (Sunderland), Dr. Forsyth (Cramlington), Dr. Fox (South Moor), Dr. Giffon (North Shields), Dr. W. Mackenzie (Gosforth), Mr. N. Macley (Newcastle), Dr. Scott Purves (Alnwick), Dr. H. Smith (Darham).  
£10.—Dr. J. T. Dunlop (Newcastle), Dr. A. Smith (Ryton).

£5 5s.—Dr. W. Fairclough (Hexham), Dr. H. E. Gardin (Newcastle), Dr. T. W. Hay (Newcastle), Dr. D. W. Inglis (Hexham), Dr. J. F. Longbottom (Middledonagh), Dr. James McDonald (Bellingham), Dr. Marked (Alnwick), Dr. Moors (Broomhill), Dr. Gavin Muir (Newcastle), Dr. H. Carden Pearson (Darlington), Dr. E. F. Pratt (London), Dr. Stanley Rodson (Howlands Gill), Dr. Eleanor Walkinshaw-Osselton (Newcastle), Dr. J. B. Williamson (North Shields), Dr. Stanley Worthington (Newcastle).

£5.—Dr. H. Dickie (Morpeth), Mr. C. D'O. Grange (Harrogate), Mr. A. S. Percival (Newcastle).

£5 2s.—Dr. Monica Bell (Hunthausen), Dr. J. Galloway (Low Fell), Dr. G. H. Harbottle (Newcastle), Dr. E. E. Norman (Newcastle), Dr. J. Wormall (Darlington).

£2 2s.—Dr. J. (Sunderland), Dr. A. (Sunderland), Dr. A. (Sunderland).

£1 1s.—Dr. Bishop (Wylam), Dr. A. Brecken (Redcar), Dr. J. Brecken (Stockton-on-Tees), Dr. J. Crumbar (Cable Douglas), Dr. Percy (Bilmond), Dr. G. Hall (Stockton), Dr. Bruce Law (Sunderland), Dr. S. Lyle (Stockton), Dr. C. V. Miller (Stockton), Dr. A. T. Thompson (Darlington), Dr. L. M. Weeks (Newcastle), Dr. Ethel Williams (Newcastle).

10s. 6d.—Dr. G. Irving (Stockton), Dr. T. Kirk (Stockton), Dr. R. Manners (Stockton).

### IODINE IN EXOPHTHALMIC GOITRE.

SM.—With reference to Dr. Fraser's paper and your leading article on exophthalmic goitre in the *BRITISH MEDICAL JOURNAL* of January 3rd, it may be of interest to know that a Swiss committee is at present investigating the morbid conditions caused by iodine, especially in connexion with the prevalence of exophthalmic goitre. Medical practitioners have been circularized on the subject, and as a result more than 3,600 cases of the disease have been notified, a number far in excess of what was anticipated.

Here in the Canton Vaud all school children receive a tablet containing an iodine preparation once a week, and in the adjoining Canton Valais the salt sold in shops is impregnated with a small quantity of iodine, as preventives of goitre. There is now a suspicion that this use of iodine, in order to prevent ordinary goitre, may be a factor in the prevalence of exophthalmic goitre, and medical practitioners have now been asked to fill in forms giving a more detailed statement of the cases that have come under their observation.—I am, etc.,

Tour de Peilz, Switzerland,  
Jan. 6th.

W. G. MACPHERSON,  
Major-General, late R.A.M.C.

### THE PASSAGE OF FOOD THROUGH THE BOWEL.

SM.—I have read with great interest the leading article in your issue of November 22nd, 1924, entitled "The passage of food through the bowel," and I shall be grateful to be permitted to make the following remarks thereon.

In 1922 I published a pamphlet, *A Study of Intestinal Stasis* (London: John Bale, Sons and Danielsson, Ltd.), in which I recorded experiments essentially similar in character to those of Alvarez and Freedlander. But my interpretation of the meaning of the phenomena disclosed by experiment differs from that you tentatively ascribe to the work of Alvarez and Freedlander. I shall briefly tabulate my interpretation thus:

1. That the residua demonstrated in the intestinal tube—especially in the colon—are an index of defective (unphysiological) function on the part of the intestinal tube.
2. That this residual phenomenon varies in degree from a slight defect in apparently healthy people to a gross and serious defect in the subjects of clinically recognizable intestinal stagnation.
3. That the residua in the bowel, being stagnant, become putrefactive and infect the whole mass of the bowel contents.
4. That the only true test of perfectly physiological function on the part of the bowel is that the faeces shall be almost entirely inoffensive—that is, no residues are left.

I believe that the due consideration by the profession of this principle—that any degree of putrefaction, slight or gross, is a departure from true physiological function and therefore a state of disease—would lead to a great reconciliation of present opposing views regarding the influence of intestinal stagnation on bowel and other disease.

In my pamphlet I gave an x-ray record of that residue which I regard as the primary and most important of all—namely, residual faeces in the pelvic colon. I also indicate clearly that my observations are but a repetition of the experiments and observations of such investigators as Stephen Hales, Kampf, and O'Beirne: the same also applies to my interpretation of the observed phenomena.

The operation which I propose for relieving pelvic

colon stagnation was recently the subject of an article by Dr. J. A. Macewen of Glasgow (BRITISH MEDICAL JOURNAL, October 11th, 1924). Elsewhere I shall draw attention to the fact that the pelvic colon residue is commonly misinterpreted in textbooks as rectal retention of faeces.—I am, etc.,

JAMES C. WATT,  
Medical Officer, W.A.M.S.

Medical Department, Tarkwa, Gold Coast,  
West Africa, Dec. 11th, 1924.

### FREUDIAN DOCTRINE.

SIR,—The kind of discussion proposed by Dr. Ernest Jones in your issue of January 10th (p. 93), in which he comments on my letter published on December 20th, 1924, is very different from that which I suggested as desirable. Nor can I admit that a mere review of criticisms adverse to psycho-analytic theory and practice, especially when written by psycho-analysts, can be rightly regarded as scientific discussion. Dr. E. Jones maintains, in reply to my statement that no adequate discussion of psycho-analysis among well accredited medical and psychological authorities has as yet been held, that, in his opinion, such discussions have already taken place; and, among others, he cites one where psycho-analysis was dealt with at a meeting of the Royal Anthropological Institute. This, however, took place on the occasion of an address by the President of the Institute and a following paper read by Dr. Jones, on the relation of anthropology and psycho-analysis, of which no criticism was made and to which no subsequent replies were admitted.

I did not diverge materially, if at all, from the truth in what I wrote in my letter to you; and can repeat confidently my statement concerning the non-existence of any adequate criticism by leading psycho-analysts of the two books by Dr. Wollheimuth, D.Sc., and Dr. P. McBride (correctly identified by Dr. Jones).

Whether the contentions in these books and other less detailed criticisms that have appeared are sound or not, they cannot be ranked as merely the outcome of ignorance and rancorous abuse, such as Dr. Jones rightly regards the hostile comments he deems unworthy of notice.—I am, etc.,

London, W.2, Jan. 13th.

BRYAN DEXTER.

### TREATMENT OF PERFORATED GASTRIC AND DUODENAL ULCERS.

SIR,—In the JOURNAL of January 3rd (p. 12) Mr. Percival Mills raises an interesting and important point in connexion with the treatment of perforated gastric and duodenal ulcers. He considers that it is advantageous to perform gastro-jejunostomy at the same time as the perforation is sutured, and his statistics appear to show that patients so treated do better and have a shorter convalescence than those who do not undergo the short-circuiting operation. In this view he is supported by many surgeons, one of whom (Deaver) has published a very striking series of 56 perforated ulcers operated upon (in all but two with simultaneous gastro-enterostomy) with only 2 deaths; if these wonderful results were certainly due to the performance of the anastomosis it would be the duty of every surgeon to adopt that technique, but such results have to be scrutinized carefully because they are contrary to the experience of many surgeons. The results that Mr. Mills publishes are very creditable, but do not, in my opinion, show such a great difference from the average results at the present day. To ascertain the average mortality I have examined the notes of all cases of perforated ulcers admitted to St. Mary's Hospital during the five years 1920-24. (For the great trouble and care he took in collecting these data I wish to thank Mr. G. D. Robertson, F.R.C.S., very sincerely.)

It appears that during the five years investigated 67 cases of perforated ulcers were admitted, and that of these 17 died—a mortality rate of 25.5 per cent. Since this list includes three moribund and unoperated cases the mortality represents the maximum. I agree with Mr. Mills in considering it wise to include all cases, for in the favourable report of Deaver many moribund and inoperable or unoperated cases were not included in the series. The patients in the St. Mary's series were operated upon by

nine different surgeons, so that the results should be regarded as typical of present-day results. Some of the cases had gastro-enterostomy performed at the same time as the ulcer was sutured, others had not. Those who had the anastomosis performed certainly did better than those who simply had the ulcer sutured, but the time factor seems to have played an important part in producing this result. Of the 40 cases in which the time elapsing between perforation and suture is mentioned 24 underwent simple suture with 8 deaths; while of the 16 who also had a gastro-enterostomy performed only 3 succumbed. But the average lapse of time between the perforation and operation in the first group of cases was thirteen hours, whilst in the second it was only five and a half hours, so that the time factor alone would be sufficient to account for the more favourable results.

It is therefore clear that there is room for a very thorough investigation of the question. Such an inquiry should embrace the work of many surgeons at several hospitals, and sufficient details of cases should be given to enable an impartial judge to give an opinion. To form anything like a reasonable and impartial judgement we should be informed as to the age of the patient, the position of the perforation and whether the ulcer was acute or chronic, the time elapsing between perforation and operation, the amount of peritonitis and the degree of shock or toxæmia from which the patient was suffering. It is indicative of the uncertainty existing on the question that, whilst Mr. Mills is performing gastro-enterostomy more frequently, I find myself doing it not so often as formerly. I am fully aware of all the arguments that have been put forward in favour of the combined operation, and used to argue in its favour myself. I now think that it is only occasionally advisable, and agree with Mr. Mills that "considerable judgement is required to decide when to perform gastro-jejunostomy in these cases." The suture of a perforated ulcer has frequently to be done by those who have not a large experience of gastric surgery, and I consider it would be a pity if it were generally accepted that a gastro-enterostomy should be performed at the same time.—I am, etc.,

London, W.1, Jan. 5th.

ZACHARY COPE.

SIR,—Judging by Mr. G. P. Mills's paper, the question of the proper treatment of such catastrophes as perforation of gastric and duodenal ulcers seems to have been settled for surgical specialists. For the general practitioner surgeon the decision is much more difficult. Whilst he knows that he probably would save those sutured cases that die from hæmatemesis or secondary perforation by primary gastro-enterostomy, on the other hand the time he consumes in posterior gastro-enterostomy, and the prolonged etherization, would probably sacrifice a larger number of cases.

Whilst believing that suture and gastro-enterostomy is the correct treatment, I am of opinion that for the general practitioner surgeon simple sero-serous suture and over-sewing of omentum is the safest course. I have performed twenty to thirty such operations with three fatalities.—I am, etc.,

JOHN H. TONKING, M.B.Lond.

Camborne, Cornwall, Jan. 5th.

### ACIDOSIS AND ACETONAEMIA IN RELATION TO SEA-SICKNESS.

SIR,—Although I have been going to sea, off and on, for thirty-one years, I never associated acidosis and acetonaemia with sea-sickness until I held the appointment of surgeon to the steadiest ship I have ever been on, where there are comparatively very few cases of this complaint.

What drew my attention to it, I think, was the extraordinary number of cases in women in the middle or late stage of pregnancy, who, having ceased vomiting in the early months, commenced vomiting again after coming on board, and some cases of intractable vomiting in children, when the movements of the ship were so slight as to be out of all proportion to the illness of the patients. The children often had a previous history of cyclical vomiting. My investigations, covering a period of three years,

have shown me increased acid and acetone in the urine in all cases of apparent sea-sickness with the exception of two, which came under my notice only recently, and made me doubt the conclusion I had come to, that all cases of sea-sickness were due to or accompanied by acidosis and acetonaemia. It almost made me wonder whether these two cases were simple sea-sickness after all. In a great number of cases acetone can be detected in the breath of the patient. I should like to have the observations of other ship surgeons on the prevalence of acidosis and acetonaemia amongst cases of vomiting at sea. Although sea-sickness may not be due to these causes, the presence of acidosis and acetonaemia in such a very large proportion of cases seems worthy of thorough investigation. That the acetone present is not due to starvation is amply proved by the fact that some persons are sea-sick shortly after the ship sails—some even declare they are nauseated before the ship moves from the dock, and one patient declared that the mere walking along the dock before embarking was sufficient to cause a feeling of nausea. It would seem likely that the sympathetic system may act on one or more of the endocrine glands, possibly the pancreas, and so cause the fats to be broken up into these substances instead of carbon dioxide and water, as we know happens in diabetes. At any rate it is interesting to note that these cases respond very readily to intensive alkaline treatment (especially children); the worst cases have to be treated by high rectal injections, and when vomiting ceases, as it often does in an hour or two, the treatment is continued by mouth. It is almost like a conjuring trick to see a child, who has been lying in bed and vomiting everything ingested, up and about playing in a few hours. I have added glucose to these rectal injections, but clinically this does not seem to be a success, though theoretically it would appear to be indicated, and I have consequently discontinued it. For the rectal injections I use sodium citrate (1 drachm to a pint), repeated according to retention and results, and grape fruit and oranges or lemonade by the mouth when they can be retained, as they often are almost immediately. By the mouth sodium citrate is given, from a maximum dose of half a drachm every two or three hours downwards, according to retention, severity, and age (after vomiting has ceased or become less frequent following the rectal injections), often combined either with nux vomica or sodium bromide, according to whether the case is asthenic or sthenic as determined by the pulse. The former is, in my observation, far more frequently the case, and the patient also most often requires stimulating to counteract the depressing effect of the alkaline treatment; in milder cases a bismuth citrate mixture is effective.

In conclusion, these investigations have shown in my practice that more than 99 per cent. of cases of vomiting at sea, not due to an obvious organic lesion, have been accompanied by increased acidity and acetonaemia; the sickness clears up quickly under an intensive anti-acid treatment, and it would seem to follow that it is advisable to have any hyperacidity corrected before embarking.—I am, etc.,

B. SYDNEY JONES, M.R.C.S., L.R.C.P.,  
Surgeon, R.M.S. *Aquitania*.

Southampton, Dec. 15th, 1924.

#### THE RURAL PRACTITIONER AND MATERNITY.

Sir,—Appreciation is oftentimes greatly cheering, and I trust an abler pen than mine will record our thanks to Dr. Mottram for his very able, truthful, and convincing article in your issue of January 3rd (p. 41).

The troubles, trials, and difficulties that confront a rural practitioner are forcibly related, and from nearly fifty years' experience I can fully substantiate, and could find cases in support of, his statements. The paragraph on notification brought to my mind a case that occurred many years ago. In a small crowded cottage, with a family of eight children, one child, ill with diphtheria, developed acute appendicitis. There was no isolation or fever hospital or cottage hospital, and a general hospital was out of the question. The medical officer of health could render no

aid, but finally, after much trouble, the infectious hospital of one of our large towns admitted the case.

After the return of the child I was personally charged with the cost of maintenance, etc., for the period of detention. Fortunately for me the Poor Law authorities discharged this liability. The paragraphs on midwives and finance are clear and correct, and will be verified on many sides, and with Dr. Mottram's concluding remarks and suggestions most practitioners will be in agreement.

In later years the provision of two cottage hospitals in this district has already been a great boon, and will be more fully appreciated by the coming practitioners.

The increasing use of motors and their availability has simplified some of our difficulties, but in urgent cases we have still to make use of the larger hospitals situated fifteen, twenty-five, and thirty miles distant. May I be allowed to record my deep sense of gratitude to the authorities and staffs of the general and special hospitals (especially of Manchester) for their unflinching promptitude and willingness to accept and treat cases under all sorts of conditions and times? This kindness has extended over many years, much relief has been given, and very many valuable lives have been spared.—I am, etc.,

Tideswell, Jan. 5th.

THOMAS H. PARKE.

#### TONSILLECTOMY.

Sir,—Dr. Tawse, in the issue of the JOURNAL for December 27th, 1924, ventures to prophesy that "the unnecessary waste of blood by the guillotine method will be the direct cause of dissection being generally adopted by the laryngologists of the next generation." If Dr. Tawse can find time to visit the operation clinics of the great majority of the younger school of laryngologists attached to the staffs of the metropolitan hospitals, he will not be so sanguine of the likelihood of his prophecy being fulfilled. Indeed, any support he may obtain for his views will, for the most part, come from the older school of surgeons, who for one reason or another have never troubled to give the "reverse guillotine" method a fair trial. Dr. Tawse states that "some laryngologists have, partially or wholly, abandoned the guillotine in favour of dissection." I venture to doubt this statement. I have never met them.

I served my apprenticeship in the atmosphere of the dissection school associated with the name of G. E. Wagh, and to him the great credit must be given for describing in 1909 his technique for the dissection of tonsils, a method which will find its use even in the hands of the most skilled manipulator of the "reversed guillotine." I agree with all that Mr. T. B. Layton has stated, and I would like to add a quotation from an article of mine in the *Lancet* of January 22nd, 1921, on "A study of the indications for the removal of tonsils by the dissection or by the reverse guillotine":

"... If tonsils can be adequately removed by a simple, short operation, entailing less discomfort, less risk, shorter convalescence, and less expense to the patient, surely this operation should commend itself to the surgeon anxious to do his best for the patient."

May I in my turn hazard the prophecy that the next generation will, in still greater numbers than the present, continue to enucleate tonsils by the reverse guillotine method, and will only dissect them out when they are compelled to do so? Finally, may I express the pious hope that another and still better method will be evolved, which will put an end to party discussion and thus free your valuable space for more profitable correspondence?—I am, etc.,

London, W.1, Dec. 26th, 1924.

M. VLASTO, F.R.C.S.

#### WOMEN DOCTORS.

Sir,—As showing the glut in women doctors, the following figures may be of interest. To-day there were seventy-eight applicants for the post of junior resident medical officer (female) at the Children's Hospital, Sunderland; salary £100 a year.

Thirty-three held English qualifications, thirty-three Scottish, and twelve Irish. Of the English qualifications 10 were London degrees, 4 Durham, 2 Birmingham, 1 Sheffield, 7 Manchester, and 6 were London Conjoint diplomas. Of the 33 Scottish qualifications 3 were of

St. Andrews, 9 of Edinburgh, 13 of Glasgow, and 8 of Aberdeen. Of the 12 Irish qualifications 7 were of Belfast, 3 of Dublin University, and 2 of Irish Conjoint Colleges.

Forty-five out of the seventy-eight candidates had held previous public appointments, and many of them had held several.—I am, etc.,

Sunderland, Jan. 13th.

WM. ROBINSON.

## Obituary.

LILLIAS HAMILTON, M.D.Brux., L.R.C.P. and S.Ed.

At the present time, when the study of medicine is regarded as an accepted career for women, it is with admiration for the undaunted spirit of a pioneer that we record the death of Dr. Lillias Hamilton. The eldest daughter of Hugh Hamilton of Ayrshire, she was born in New South Wales, her mother's country. She was brought to England in childhood, and was educated at Cheltenham. It was due to some words of Miss Beale that Miss Hamilton determined on medicine as her career. She trained first as a nurse in the Liverpool Infirmary, and then studied medicine at the London School of Medicine for Women, and at Edinburgh University. She took the diplomas of L.R.C.P. and S.Ed. in 1890. She studied also in Brussels, Vienna, and Stockholm, and took the M.D.Brux. in 1890.

Dr. Hamilton went to India and established a private practice in Calcutta, where she was also physician in charge of the Dufferin Hospital. After an attack of cholera in 1894 she was obliged to take a rest, and made the journey to Kabul. During her visit there the favourite wife of the Amir (the late Abdur-Rahman) was ill and Dr. Hamilton was requested to attend her. She was then offered the post of court physician, which she held for four adventurous years. Some of her experiences of this time are given in her book *A Vizier's Daughter*, published in 1900.

The magnitude of her work in that isolated country, previously uninfluenced by Occidental ideas of hygiene, cannot be estimated. One of her triumphs was the compulsory introduction of vaccination for children. Her life there must have been one of inconceivable difficulty, constantly fighting against superstition, ignorance, and the jealousies of an Eastern court. But the pioneer spirit of Dr. Hamilton, who exhibited exceptional pluck and enterprise, was undaunted by the many and peculiar difficulties of her position. Her house in Kabul gradually became a hospital, in which she was helped by her sister, and later by an English nurse. Failing health obliged her to relinquish her appointment in 1898, when she returned to England.

For the next few years Dr. Hamilton practised in London. In 1902 she became warden of Stndley Horticultural and Agricultural College for Women, Warwickshire. Her great desire was to add to the number of careers open to women, and especially to give them healthy occupation. To this undertaking she gave generously, not only of her health and energy, but also of her fortune. After many difficulties, she was successful in seeing Stndley recognized as one of the two leading training schools of horticulture for women in this country. One of the students she trained is now principal. In spite of health so indifferent that years ago it would have entitled her to rest on her laurels, she remained warden of the college until last year. During the war she recognized the prior claim of medicine, and in 1915 went to Montenegro to take charge of a hospital, and remained there until the general retreat through Serbia.

Dr. Hamilton had travelled extensively, and had a wonderful facility in languages. Her versatility was well recognized among her associates, and her conversation was admittedly brilliant. Her forceful personality and her habit of looking at main issues rather than considering petty details had an invigorating effect on a community of women. Her students learnt far more than technical training from her leadership. Never sparing herself or others—for she considered work to be salvation—her generous understanding of human nature nevertheless made

her always ready to give sympathy and help to those in need.

Besides the book mentioned above Dr. Hamilton wrote *A Nurse's Bequest*, published in 1907, and *The Powers that Work in Darkness*, published in 1924. She died at Nice on January 6th.

FREDERICK LOCKHART, M.B., C.M.EDIN.,

M.D., C.M.McGILL,

Clinical Professor of Gynaecology, McGill University.

A REUTEN's telegram from Montreal, dated January 12th, announced the death of Dr. Frederick Lockhart, professor of gynaecology at McGill University. It appears that during a hunting trip in the St. Maurice Valley he was lost in the woods, and his legs were severely frostbitten; this eventually caused his death. Frederick Albert Lawton Lockhart received his medical education in the University of Edinburgh, where he graduated M.B., C.M. in 1889. In 1900 he received the degrees of M.D., C.M.McGill. He was professor of clinical gynaecology in McGill University, and gynaecologist to the General and Verdun Hospitals.

We are indebted to Sir ALEXANDER HOUSTON, K.B.E., M.B., D.Sc., Director of Water Examination, London, for the following tribute to Dr. Lockhart's memory:

Lockhart was at Merchiston from 1881 to 1884, and endeared himself to all his schoolfellows by his charming and sterling qualities which throughout the rest of his distinguished career attracted all and sundry with almost magnetic force. About that time Merchiston was rich in Scottish rugby internationalists (Campbell, Begbie, Anderson, Roland, Goodhue, and Neilson), several playing while still at school, and although Lockhart's abilities lay in other directions he had such an immense natural love of sport that the glamour of his school-fellows' athletic performances may well have stirred his ambitions profoundly, and led him to determine to add to the glories of his old school in a larger world. In those early days, and later at Edinburgh University, he was plodding rather than brilliant, but always he gave the impression of a man slowly but surely building up the foundations for a great career. He had a simple faith in his fellow creatures, and this, combined with a naturally unselfish disposition, goes far to explain the great influence he was destined to exert on medical and social activities in Montreal. After he graduated our ways gradually fell apart; our friendship was so great that, perhaps like most busy men, we thought it hardly necessary to keep it cemented by correspondence. Yet the years brought me news of him from outside sources from time to time of his great skill in the branch of the profession which he so much adorned, and frequently, as well, came the added information, so dear to his old friend, that his kindness and generosity to the poor and lowly was proverbial in Montreal.

When I went to Ottawa in 1913 to report, in conjunction with the late Sir Alexander Binnie, on the water supply, Lockhart begged me to break my return journey at Montreal and stay with him. It is a solace to me now to remember that I gladly acceded to his request, and to recall our last meeting, so full of happy reminiscences of our schoolboy and college days. I well remember the pride with which he showed me a fine specimen of that sporting fish, the black bass, which he had caught in one of the Canadian lakes, and I learnt that his greatest joy was to fish and shoot in these wild regions. Now, alas, he has had his last adventure, and the world is much the poorer.

Dr. EUGENE C. MCCARTHY died at Stalybridge on December 26th, 1924, aged 65. He was a native of Tyneside and studied medicine at Owens College, Manchester, graduating in 1892 M.B., Ch.B.Vict., with honours and distinction in obstetrics and gynaecology. Two years later he went to Stalybridge, where he built up a large practice and won the esteem and regard of all his patients. Amidst the claims of a very busy professional life he found time to take an active part in the public affairs of the district. For some years he represented the Dukinfield ward of the Ashton Board of Guardians, and was surgeon lieutenant in the old Stalybridge detachment of the 4th Battalion of the Cheshire Regiment. He was appointed a justice of the peace for the borough of Stalybridge in 1895, and was a member of the Hyde Division of the British Medical Association. Dr. McCarthy retired from practice about ten years ago. At the funeral the mayor and mayoress of Stalybridge were present, as well as representatives of the magisterial bench.

A FRESH course of post-graduate lectures (free to medical practitioners) was commenced at the Hospital for Sick Children, Great Ormond Street, W.C., on Thursday last, when croup was discussed by Dr. Pearson. On Thursday next, at 4 p.m., Dr. Frew will speak on tonsils and adenoids. The lectures will be continued on succeeding Thursdays at 4 p.m. up to and including April 2nd.

THE spring courses of lectures and demonstrations at the Royal Sanitary Institute (90, Buckingham Palace Road, S.W.1) start on January 26th, at 5.30 p.m., with an introductory lecture by Professor H. R. Kenwood, C.M.G. The course for sanitary officers begins on January 28th, and comprises the subjects for examinations of the Institute and the Sanitary Inspectors' Examination Board. The course for health officers and child welfare workers begins on January 30th, and is intended as a preparation for the health visitors' examination of the Royal Sanitary Institute. The course for meat and food inspectors begins on February 5th.

AT a meeting of past and present women students of St. Mary's Hospital, London, held on November 27th, 1924, it was decided to form an association, to be known as the St. Mary's Medical Women's Association. Its objects are those of a social club and a mutual aid society. Any woman from St. Mary's who may not have received notice of its formation is asked to communicate with the Honorary Secretary, Mrs. Bolton, East Wcald, Bishop's Avenue, N.2.

THE Royal Sanitary Institute will celebrate next year the jubilee of its foundation. It was founded in 1876 to aid in carrying out the provisions of the general Public Health Act of the previous year.

THE Central Midwives Board for England and Wales met on January 8th, with Sir Francis Champneys, Bt., in the chair. The Board dealt with a letter from the Ministry of Health suggesting a further alteration in the new rules as to training. It was decided that during the remainder of the year the usual day of meeting of the Board be the first Thursday in each month (except August and September).

THE King of Italy has conferred the Grand Cross of the Order of the Crown of Italy upon Dr. A. Castellani, C.M.G., physician to the Italian Hospital, London, and lecturer in the London School of Hygiene and Tropical Medicine.

THE Astor silver challenge shield, awarded annually by the National Baby Week Council for the most effective Baby Week campaign, has been won for 1924 by Leicester Health and Baby Week Committee. Hull and West Bromwich came next in order of merit, each receiving the same number of marks.

THE sum of £55,643 has been raised as the result of the recent dinner of the Lord Mayor of London at the Mansion House in aid of St. Thomas's Hospital.

AT the twenty-first congress of the Italian Society of Dermatology held at Padua recently papers were read by Professor Tommasi on the treatment of syphilis and by Professor E. Bizzozero on experimental cancer.

THE *Archivio Italiano di Otolologia, Rinologia e Laringologia*, which has hitherto been published every two months, has now become a monthly publication.

DR. C. LADAME has been appointed to the chair of psychiatry in the University of Geneva in succession to Dr. R. Weber, who has been made emeritus professor.

## Letters, Notes, and Answers.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

The telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange). The telegraphic addresses are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER, Aitology Westrand, London.

Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

### QUERIES AND ANSWERS.

"P. A. R." asks for advice as to the best apparatus to help an ordinary case of senile deafness.

#### DERMATITIS EXFOLIATIVA.

DR. M. W. BROWDY (London) writes: I would advise "B. A." to give non-specific protein therapy a trial. Occasionally remarkable results are obtained.

#### INCOME TAX.

##### Subscriptions.

"A. W." holds a public appointment and is claiming deductions from the assessment on his salary in respect of subscriptions to medical societies and institutes and for maintenance of his professional library. The deductions have been refused, and "A. W." has given notice of appeal.

\* \* These expenses would be allowable if the profits were chargeable according to the rules of Schedule D; the question is

whether, as the revenue authorities contend, they are excluded by the stricter rule of Schedule E, under which the emoluments of a public office are assessed, which is as follows: "If the holder of an office . . . is necessarily obliged to incur . . . out of the emoluments thereof the expenses of travelling . . . or otherwise to expend money wholly, exclusively, and necessarily in the performance of the said duties there may be deducted the expenses so . . . incurred." The view taken by the authorities is that expenses of this kind are not "necessary," unless the appointing authority requires the officer to be a member of the society or institute as a condition of his retaining the appointment. This is a strict application of the word, but it must be admitted that it is difficult to qualify it. A judgement delivered within the past two months by the Master of the Rolls, in the case of *Ricketts v. Colquhoun*, contains observations which, although the expenses by "A. W." were in some ways dissimilar from those under discussion, suggest that the courts would apply this rule strictly—for example:

"It is the duty of this court to adhere closely and accurately to the actual words of Rule 9, which are of general application to all holders of offices which come within its ambit," and "I think the words 'necessarily obliged' are to be read as meaning this, that where an obligation is imposed upon the holder of an office which *ex necessitate* of the office compels him to make outlays . . . it is after you have fulfilled that condition that you first begin to consider what is the possible expenditure that may be deducted."

It will be seen that the trend of these observations is towards the Revenue point of view, and we do not think "A. W." is likely to succeed unless he can show that the appointing authority stipulates for membership, etc., and so can bring himself within the *ex necessitate* condition.

#### Arrears.

"A. K." received on December 24th, 1924, a demand for alleged arrears of tax for 1918-19, that being the first intimation received that any arrears were claimed. He asks: Is there any time limit in such cases?

\* \* An assessment to income tax for the year 1918-19 is invalid unless made by April 5th, 1922. If the assessment in question were made in time it is difficult to understand why "A. K." was not notified thereof before December 24th, 1924. We suggest that he should tell the collector that he did not receive any previous notice of the assessment, and that he wishes to be informed (1) when the assessment was signed by the Commissioners, (2) when the formal statutory notice was issued, and (3) to what address it was sent.

#### Assessment of Firm.

"C. C. E." bought a one-fifth share in a practice as from April 1st, 1924. The inspector of taxes refuses to allow him to deduct from his share of the firm's income tax assessment his own expenses subsequent to April, 1924.

\* \* This is correct. His liability is not direct but only as a member of the firm; it is the firm which is assessable on the past average profits of the practice, and only the expenses incurred in the years covered by the period of average can be deducted. It may be added that the acceptance of "C. C. E.'s" claim would lead in most cases to the double allowance of expenses incurred in such circumstances. He may, however, wish to hear in mind the fact that if from some specific cause (to be alleged and, if required, proved) the profits of the firm fall off in the year 1924-25, then the whole firm (not merely "C. C. E.") can claim to have the average assessment set aside and the actual net profits of the practice substituted.

#### Receipt of Rent for Rooms.

"L. A." refers to an answer given in our issue of December 13th, 1924, and supplies some further particulars. His account has been advised that the receipt of rent for unfurnished rooms should not reduce the amount previously claimed as representing the professional portion of the premises.

\* \* It is assumed that the premises form an undivided whole. "L. A." is entitled to deduct such a portion of his rent as is reasonable. We are of opinion that a claim to exclude consideration of the rent received for the subletting would not succeed on appeal. The obvious intention of the statutory provisions is to allow proper amounts for expenses, and unless the rent received is set against the rent paid before a proportion the result is to make an allowance which would be unreasonable. For example, on the ordinary 50 per cent. basis of division the claim would work out on that basis as follows:

Rent and rates paid . . . . .	£25 0 0
Proportion applicable to practice . . . . .	12 10 0
Rent and rates received from subletting . . . . .	13 0 0

It seems impossible to allege that it is reasonable to deduct £12 10s. when the house costs £25 only inclusive of the private portion of the premises.

## LETTERS, NOTES, ETC.

## MOTOR CAR INSURANCE.

THE secretary of the Medical Insurance Agency (429, Strand, W.C.2) asks us to say that the Agency has lately received inquiries about motor car insurance from three members of the British Medical Association who omitted to send their names and addresses, and he is therefore unable to send particulars. The first inquiry was from York for insurance of a 22-h.p. 1924 Chrysler car, value £550; the second was from Crumlin, Co. Antrim, regarding a 10.9-h.p. 1925 Galloway car, value £175; the third was from Belfast regarding an 11.9-h.p. 1917 Morris Cowley car, value £150.

## RAIN-BEARING WINDS AND EARLY PHTHISIS.

DR. H. BAZETT (Torquay), in the course of a letter on Dr. William Gordon's address and the correspondence which ensued, writes to congratulate Dr. Gordon on having established his conclusions, and suggests two reasons why west and south-west winds have a deleterious effect on phthisis. Dr. Bazett states that he went from Thorncombe, in Dorset, at an elevation of from 600 ft. to 800 ft., to Torquay. The chief effect he noticed of the change to the sea coast was the depressing effects of these winds. When warm they seemed to have the same effect as was produced inland by "thunder in the air"—headache, lassitude, and mental depression. The winds are frequently cold, and when this is the case the cold is exceptionally penetrating. His second point is that a large proportion of phthisical patients suffer also from bronchial catarrh, the symptoms varying in intensity with the amount of moisture in the air. Dr. Bazett suggests that the statistics of simple phthisis should be separated from those of phthisis complicated with bronchitic conditions. At Torquay, which is on a promontory exposed to sea breezes on three sides and presenting hills intersected by valleys, it is possible to obtain every variety of shelter and every modification from the relaxing air of the front to the highly bracing air of the hills.

## CAESAREAN CHILDREN.

A CORRESPONDENT, "O. H.," has sent us a letter he received from the rector of the parish in which he resides. The rector was called upon to baptize twins, a boy and a girl; the names given by the mother were Yvonne Julia and Henry Caesar. When registering the names the rector made a judicious inquiry as to the reason for their selection; the mother replied, "They are children of a Caesarean incision and I thought it ought to be remembered in their names." We had heard that Sir Francis Champneys, when at St. Bartholomew's Hospital, used to try to persuade the parents of children born by Caesarean section to have them baptized Caesar or Caesarina, according to sex, as a perpetual reminder. In reply to our question, he writes: "With how many I succeeded I have no idea. Such a thing as the name of a child would not have been recorded in the ward notes."

## COMPLETE TRANSPOSITION OF VISCERA.

CAPTAIN N. C. KAPUR, I.M.S., writes: Cases of complete transposition of viscera are not very common, so that the following details are of some interest. A Hindu boy, aged 8 years, attended the out-patient department of the Medical College Hospital, Calcutta, for kala-azar. Palpation of the abdomen revealed a tumour in the right hypochondriac region extending downwards and inwards to about the level of the umbilicus. This tumour had a splenic outline, and there was a distinct notch in its anterior margin. The liver was felt in the left hypochondrium and was slightly enlarged. The boy was admitted to hospital, and x-ray examination showed the heart on the right side of the chest. Skiagrams of the abdomen taken after a bismuth meal showed that the stomach was situated mainly on the right side of the abdomen, with its cardiac end under the right cupola of the diaphragm and the duodenal bulb on the left side of the middle line. The caecum and the ascending colon were found on the left side. The descending and the sigmoid portions of the colon were situated on the right side of the abdomen.

## POISONING BY POTASSIUM CYANIDE.

"J. B. S." writes: A recent case of poisoning reported in your issue of January 3rd (p. 56). I should like to ask what is the most effective treatment for poisoning by cyanides, and especially that available in surgery or home. Christison's Treatise on Poisons, fourth edition, page 778, quotes several authorities, including Orfila, giving chlorine and ammonia as effective antidotes, especially chlorine. I know that the ammonia bottle was kept in readiness in a manufacturer's laboratory for assistants who succumbed to transient but startling effects of prussic acid fumes. This would be about 1855. With respect to chlorine, of which Orfila says, "the most powerful antidote of all hitherto considered," this could be easily made in the surgery in a few minutes—for example, Burney Xeo's mixture. I used some years ago solution of chlorinated soda to estimate cyanides quantitatively by the temperature evolved; solutions are decomposed in ten seconds, as rapidly as ammoniacal salts, but the caustic effects after—should they be met by plenty of water? The antidotes of modern toxicologists, of "oxygen inhalation," also of "four grams of sulphate of iron and four of carbonate of soda in a glass of water," are rarely at hand; again, the cyanides of commerce should be alkaline enough, for they are rarely up to strength. Five cubic centimetres of solution of chlorinated soda (B.P.) I should expect, if of proper strength, to break up

four grains of pure potassium cyanide—perhaps eight grains of the commercial cyanide—in ten seconds, but what compounds are formed I do not know; the amount of tissue destroyed by the chlorine would be about equal to the chlorinated soda solution, in six minutes, of which two-thirds would be the first minute. I once left a chip box containing some rather pure pencils of potassium cyanide at my bedside, and was overcome by the fumes affecting me in the night; the sensation which impressed me most was that I had become free and could pass through the bedroom walls. I hope some expert will give us his experience and advice with respect to the best method of meeting cases of cyanide poisoning.

## WOMEN MEDICAL MISSIONARIES FOR INDIA.

IN the course of a letter on the need for women medical missionaries to volunteer for India, Dr. J. Walter Carr, C.B.E., F.R.C.P. (Consulting Physician to the Royal Free Hospital), writes: During the last few years many hundreds of women have qualified as medical practitioners. Now that the special conditions which existed during the war have passed away there are melancholy stories of forty, fifty, or even sixty women applying for a single one of the comparatively few posts which are open to them. In the near future hundreds more women who are now studying medicine all over the kingdom will be obtaining their diplomas. In these circumstances it is sad and surprising to learn that in India there are mission hospitals actually closed because no women doctors can be found to staff them. Among the recently qualified medical women surely there must be some who will respond to the pathetic appeal of these empty hospitals in the East. Years ago, when women were fighting their way into medicine, one of their chief appeals was that they would be able to give what it was impossible for men to render—help and service to women in the East. It would be strange and disappointing if, now that they have gained everything for which they were then striving, medical women were found unwilling to carry out the responsibilities they formerly said they were so anxious to undertake. We may be certain that our Empire in the East will last only so long as we use it, not for national aggrandisement, but for the benefit of the millions we have been called to rule and whose destinies we can largely influence.

Appended to Dr. Carr's communication is a note by Dr. Elsie Warren, D.T.M. and H. Cantab. (acting medical secretary of the Zenana Bible and Medical Mission), who states as follows: As mentioned by Dr. J. Walter Carr, wealth is not for medical missionaries. To other than honorary workers we had better say at once that we can only give a salary which is little more than a living allowance. Furnished quarters are provided and allowances for necessary travelling expenses, outfit, and language teacher. Doctors, as well as others, usually pay £12 a year towards the cost of a pension. If a worker should resign for other reason than ill health she is usually asked to refund part of her outfit and passage money. Good references are needed, and medical women need to know a little about missionary and theological difficulties before sailing. It is said, Dr. Warren continues, that the humbleness of youth helps some people to perform magnificent exploits! We try to avoid "squashing" any applicant for a post, and if (owing to her theological views) we should think her suitable for some other missionary society, though not for our own, we should say so, and offer to help her to get into touch with that society. Our work is interdenominational, and those who write to me at 33, Surrey Street, Strand, W.C.2, making a definite offer of service are asked to fill in forms of application. Some prefer to ask questions first and to see the committee later. Purlough becomes due after four or five years.

## IODINE IN GOITRE.

DR. R. R. COYLE (Glasgow) writes that he has for thirty years treated goitre with five-drop doses of tincture of iodine (B.P.) three times a day. He found this beneficial, but larger doses did harm.

## CORRECTIONS.

DR. EDWIN G. B. CALVERT asks that in his paper on "Chronic renal disease," published last week (p. 64), the following corrections, which he overlooked in proof, may be made: (1) P. 64, para. 5, line 4: "four-hourly specimens" should read "four hourly specimens." (2) P. 66, col. 2, line 4, should read "the former that have been investigated." (3) P. 66, col. 2, middle, should read "full cardiac defect," instead of defect.

THE tour to Timbuctoo which, as we announced a few weeks ago, had been arranged by the Citroën Company, has been cancelled, owing to unrest among the tribes.

THE receipt, and subsequent consumption, of two sample boxes of Player's "No. 3" Virginia cigarettes—one with cork tips and one plain—induces us to tell those of our readers who are victims to the habit that this is an agreeably mild and well made cigarette at a moderate price.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 38, 39, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 43.

## An Address

ON

THE SPHINCTERS OF THE ALIMENTARY  
CANAL AND THEIR CLINICAL  
SIGNIFICANCE.DELIVERED BEFORE THE MANCHESTER MEDICAL SOCIETY,  
(OCTOBER 8TH, 1924)

BY

ARTHUR F. HURST, M.A., M.D. OXON., F.R.C.P.,  
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

The sphincters of the alimentary canal play a very important part in digestion. Disturbances in their functional activity are not at all uncommon and give rise to a variety of symptoms of great interest.

In order to understand the nature and significance of these pathological disturbances in function an accurate conception of the anatomy and physiology of the sphincters is essential. Any one wishing to study the structure of the sphincters of the alimentary canal will, however, be disappointed to find how inadequately they are described in even the latest editions of the standard textbooks of human anatomy. Thanks to the work of Cunningham and of Symington respectively the pyloric and anal sphincters receive sufficient attention. But we get no clear idea of the anatomy of the cardiac and ileo-caecal sphincters, and indeed many authors entirely ignore the existence of one or both of them, whilst the pelvi-rectal sphincter is never mentioned.

The fundamental conception concerning the physiology of the sphincters depends upon the classical experiments of Bayliss and Starling<sup>1</sup> carried out in the laboratories of Guy's Hospital twenty-five years ago. They showed that peristalsis consists of a co-ordinated reflex, in which a wave of contraction, preceded by a wave of relaxation, passes down a hollow viscus. When this is extended to the action of sphincters it means that a sphincter should relax at the approach of each peristaltic wave. The conditions which modify this co-ordinated action will form the chief subject of my address to-night.

## THE CARDIAC SPHINCTER.

## (a) Anatomy and Physiology.

The point where the oesophagus joins the stomach is called the cardia, but much doubt has been expressed as to whether a cardiac sphincter exists at all. Poulton and Payne<sup>2</sup> have, however, clearly demonstrated that the lower end of the oesophagus in rabbits exerts a definite sphincter action. They also state that on cutting longitudinally through the cardia into the oesophagus after death in man the lower two or three inches can often be seen to have a thicker muscular coat than the part immediately above. From a radiological study of the act of swallowing in normal people and in patients suffering from achalasia of the cardia, we have come definitely to the conclusion that the last inch or more of

FIG. 1.—Stomach of stillborn infant, showing cardiac sphincter, a.s., with thickened circular muscle coat, and deep, pale, longitudinal rugae. D, Diaphragm, attached to centre of sphincter. P.S., Pyloric sphincter.

muscular coat and by the pallor and prominent longitudinal rugae of its mucous membrane (Fig. 1). When swallowing is not taking place, the postural tone of the circular muscle fibres of the cardiac sphincter is such that it has no

potential lumen, in contrast with the cervical and thoracic oesophagus, which have a potential lumen at least an inch in diameter, although when empty their walls collapse and so completely obliterate it. Consequently the sphincter offers a definite resistance to the passage of food, whereas the rest of the oesophagus offers no resistance at all.

The vagal and sympathetic nerve fibres which supply the oesophagus end in connexion with ganglion cells situated between the circular and longitudinal muscular coats, where they constitute a plexus, similar to the plexus myentericus of Auerbach in the intestines. Keith<sup>3</sup> has shown that this consists mainly of nodal tissue, similar to that of the auriculo-ventricular bundle in the heart, and only to a small extent of nerve cells and fibres. The nodal tissue reaches its greatest development in the part of the oesophagus immediately adjoining the stomach; this furnishes additional anatomical evidence for the existence of a specialized cardiac sphincter, though in adults there is often no obvious thickening of the circular muscle coat in this region, corresponding to that of the pyloric, ileo-caecal, and anal sphincters. The distinction is probably due to the fact that the function of the cardiac sphincter differs from that of the others in being concerned in the prevention of regurgitation of gas and fluid from the stomach into the mouth, and only to a very minor extent in the regulation of the onward passage of the contents of the oesophagus. It is consequently never called upon to resist a degree of pressure anything approaching that which the other sphincters are able to withstand.

When swallowing takes place the intrapharyngeal pressure rises; this propels the food into the oesophagus, along which it is actively conveyed by a peristaltic wave; our observations with the x rays fifteen years ago showed that this occurs almost as rapidly when a man stands on his head as when he is in the normal erect position. When the food reaches the extreme lower end of the oesophagus

FIG. 2.—Diagrams of the passage of a bolus of barium-containing food (a) through the oesophagus (O), as seen with the x rays, in successive seconds after swallowing. S, Spine; H, heart; D.D., diaphragm; C.C., cardiac sphincter; F, fundus.

its progress can be seen with the x rays to be arrested owing to the resistance offered by the closed sphincter (Fig. 2). Immediately afterwards the sphincter relaxes and the food slowly trickles through it into the stomach, but even now the lumen of the sphincter is very much less than that of the rest of the oesophagus. The relaxation of the sphincter as each peristaltic wave travelling down the oesophagus reaches it is typical of the activity of every other sphincter.

Under normal conditions, when the whole of a meal has been eaten, the cardia remains closed and so prevents the regurgitation of food, gastric juice, and gas, which would otherwise occur as a result of the positive pressure in the stomach and the negative pressure in the thorax. The intragastric pressure always remains about the same, as the tone of the muscular coat of the stomach adapts itself accurately to the volume of its contents. When the pressure is suddenly raised as a result of rapid aerophagy or of the evolution of carbon dioxide after swallowing sodium bicarbonate, the resistance offered by the cardiac sphincter becomes insufficient and gas is expelled by the mouth.

(b) *Achalasia of the Cardia* (so-called *Cardiospasm*).

Nearly every pathological museum contains one or more specimens of an enormously dilated oesophagus with a greatly hypertrophied muscular coat. The condition is a remarkable one, for no obstruction at the cardia has ever been discovered after death to account for the dilatation and hypertrophy. In the absence of organic obstruction some form of functional obstruction must be present, as otherwise it would be impossible to explain why, in spite of the violent peristalsis which eventually leads to hypertrophy of its muscular coat, the oesophagus should be so greatly dilated and always filled with a large quantity of food and watery mucus.

Since Mikulicz<sup>1</sup> in 1882 first suggested that the functional obstruction is due to spasm of the cardia the condition has been commonly known as *cardiospasm*. It is obvious that if a spasm were present it would offer considerable resistance to the passage of a bougie, and that if a bougie had once passed through the contracted cardia it would be so firmly gripped that its withdrawal would require considerable force, just as spasm of the anal sphincter offers considerable resistance to the finger and grips it tightly when once it has passed into the rectum. But using a rubber tube filled with mercury instead of a rigid bougie, I found that it dropped so easily into the stomach that it was impossible as a rule to detect any resistance when the cardia was reached. With its end in the stomach it could be moved freely up and down and finally be withdrawn without the slightest drag upon it, such as the grip caused by spasm would produce. These observations afford good evidence that no spasm is present. The anatomical evidence is equally conclusive. It is obvious that spasm, continuing for as many years as patients with this condition may live, would give rise to hypertrophy, corresponding with the hypertrophied sphincter and which results from the spasm caused by a chronic anal ulcer. But a careful examination of many specimens has shown that the last inch of the oesophagus, the part within the abdomen corresponding with what I have already referred to as the cardiac sphincter, is not dilated and there is no hypertrophy of its muscular coat. I recently saw the most striking confirmation of this when my colleague, Mr. R. P. Rowlands, exposed the abdominal part of the oesophagus in a case of enormous dilatation of the oesophagus, which was presumably accompanied by great hypertrophy of its wall, as the condition had been present for seven years and we had often watched extraordinarily vigorous peristaltic waves passing down to the cardia. The part exposed was of normal diameter, and its wall, far from being hypertrophied, was remarkably thin.

Though as long ago as 1895 Rolleston<sup>2</sup> had suggested that the dilatation of the oesophagus might be due to a "failure in the co-ordinating mechanism by which the cardiac sphincter is relaxed in swallowing," the *cardiospasm* theory held undisputed sway until, in 1910, a consideration of the facts I have just described led me independently to the same conclusion.<sup>3</sup> I believe that the functional obstruction is due to the fact that the peristaltic waves which pass down the oesophagus in swallowing are not followed, as they should be, by relaxation of the cardiac sphincter. It is not spasm, but absence of relaxation, or *achalasia* (α, not; χαλᾶω, I relax), of the cardiac sphincter which causes the obstruction.

The resistance offered by the unrelaxed cardiac sphincter can be overcome by a pressure of about eight inches of water. Consequently when a meal is taken no food passes into the stomach until the contents of the oesophagus form a column eight inches high (Fig. 5). Then, whenever anything is eaten or drunk, the cardia opens and allows food to pass till the height is again eight inches, when it closes once more. The patient, after losing a great deal of weight, finally reaches equilibrium, as sufficient food passes into the stomach at each meal to keep him alive on a low level of metabolism. He learns to empty his oesophagus by a voluntary effort, which is quite distinct from vomiting, on going to bed, as liquid would otherwise regurgitate into his mouth, and sometimes also two or three times in the day if the accumulation gives rise to serious discomfort.

Very little is known as to how *achalasia* of the cardia develops. I believe some cases, especially those beginning after middle life, are strictly analogous to heart-block, being the result of degenerative disease, or, in rare cases, of syphilis, of the nodal tissue, which Keith has shown is so well developed at the cardiac sphincter. One patient of mine had talcs, and the *achalasia* of the cardia was probably analogous to the much more common tabetic disorders of micturition. Rolleston<sup>2</sup> and Looser<sup>4</sup> have each

FIG. 3.—Diagrammatic drawings of oesophagus in achalasia of the cardia. A shows column of barium-containing food, 8 in. high, above closed cardia; B, after additional quantity of food swallowed, so that the taller column, being heavier, opens cardia and allows surplus to enter stomach; C, is return to condition of A after surplus food over the 8-inch column has entered stomach.

described a case following diphtheria; in these there may have been a vagal neuritis, the *achalasia* being analogous to what sometimes occurs in animals after division of both vagi. In one case degenerative changes were found by Kraus<sup>5</sup> in the vagi after death, and in another Pollitzer<sup>6</sup> found the vagi buried in a mass of enlarged glands. Most of the remaining cases are probably the result of some gastric or other abdominal disorder, which leads to reflex inhibition of relaxation of the cardia, corresponding with what often occurs at the pyloric and ileo-caecal sphincters. One of my patients had mitral stenosis and a very dilated left auricle, which may have been the source of the reflex *achalasia*.

I have found that the regular use of a large mercury tube (24 gauge) almost always gives great relief, and is often followed by permanent recovery. The patient learns to pass it on himself, at first keeping it in position for ten minutes before each meal, then gradually for shorter periods and less frequently, until finally he passes it only once a day, once a week, or only at long intervals whenever he feels that there is some slight return of obstruction. In the only case I have seen in which the mercury tube gave insufficient relief Mr. R. P. Rowlands divided the thin muscular coat of the entire cardiac sphincter longitudinally, and the result has been quite satisfactory, though the patient still has slight dysphagia. Treatment by forcible dilatation with Plummer's hydrostatic apparatus is painful, and has been followed on a few occasions by fatal peritonitis. We tried it twice without success before Mr. Rowlands operated on the patient already referred to.

(c) *Waterbrash and the Morning Sickness of Alcoholics.*

In the condition I have just described the cardiac sphincter never relaxes. I believe that *waterbrash* is also due to *achalasia*, but in this case relaxation is only inhibited at certain times. *Waterbrash* consists in the sudden evacuation of large quantities of watery alkaline fluid. The fluid is saliva which has been secreted in excessive quantities as a reflex result of the presence of excess of hydrochloric acid in the stomach—as, for instance, two or three hours after a meal in a patient with hyperchlorhydria associated with duodenal ulcer. The saliva is swallowed, but accumulates in the oesophagus, as relaxation of the cardiac sphincter is inhibited by increasing the acidity of the gastric contents, as Cannon<sup>7</sup> found experimentally in 1908. The evacuation of the fluid is not associated with nausea and is recognized by the patient as being quite different from vomiting; it is produced, in fact, by the same voluntary or semi-voluntary process as the evacuation of the contents of the dilated oesophagus in *achalasia* of the cardia. This explains the otherwise inexplicable fact that *waterbrash* is sometimes immediately followed by the vomiting of very acid and partly digested food, the alkaline

saliva having been separated from the acid food by the closed cardiac sphincter.

The morning sickness of alcoholics is also due to emptying of the oesophagus and not true vomiting. Mucus, secreted by the inflamed pharyngeal and oesophageal mucous membrane, accumulates in the oesophagus during the night; it is not actually swallowed, but trickles down, so that the cardiac sphincter does not relax. The colourless mucus first brought up is often followed by bile-stained fluid from the stomach, as the chronic gastric catarrh may cause actual vomiting.

### THE PYLORIC SPHINCTER.

#### (a) Anatomy and Physiology.

The pyloric vestibule is separated from the duodenal bulb by the pyloric canal, a channel about half an inch in length, which is normally closed by the tonic action of the well developed sphincter surrounding it (Fig. 4). Under

FIG. 4.—Three sections through the same specimen to show structure of pylorus. (After Symington.) A, Section through pyloric vestibule of contracted empty stomach. B, Section through pyloric canal. C, Section through duodenal bulb, showing pyloric orifice as seen from duodenum.

general anaesthesia and after death the sphincter relaxes, and the canal can no longer be clearly distinguished from the vestibule, except in infants; consequently our knowledge of the structure and functions of the pyloric sphincter under normal conditions has been derived to a great extent from radiological observations.

Until recently Cannon's theory of the "acid control of the pylorus" was universally accepted. Acid in the stomach was supposed to cause relaxation of the sphincter, whereas acid in the duodenum caused its contraction; thus the duodenal contents were prevented from becoming too acid, as no further chyme could pass the pylorus until that already present in the duodenum had been neutralized by the alkaline pancreatic and intestinal juices and bile. That the matter was not so simple seemed, however, to be clear from the fact that the stomach emptied itself at the normal rate or unusually fast in cases of achylia gastrica, in which there is no acid in the stomach to stimulate the opening of the pylorus. The recent investigations of Baird, Campbell, and Hern<sup>11</sup> at Guy's Hospital on healthy men with one tube in the stomach and another in the duodenum show that the acid control of the sphincter is only one of several factors controlling the activity of the pylorus. Carlson and Litt,<sup>12</sup> experimenting on anaesthetized animals, found that the introduction of sodium bicarbonate into the duodenum is as effective a stimulus to closure of the pylorus as hydrochloric acid, and that acid in the stomach had no effect at all. These observations do not prove that Cannon's conclusions from his radiological experiments on healthy cats were erroneous, but that his generalization was too sweeping.

The investigations of Thomas and Whealon<sup>13</sup> and of Carlson and Litt<sup>12</sup> have shown that the pyloric sphincter is supplied with both motor and inhibitory fibres both by the vagi and the sympathetic nerves, the character of the response to any stimulus depending upon the tone of the sphincter at the moment. The work of various other investigators proves, however, that the main effect of the vagus on the pyloric sphincter is to cause relaxation, and the main effect of the sympathetic is to cause contraction.

The pyloric canal opens under normal conditions on the approach of every peristaltic wave from the very beginning of digestion, before free acid has appeared in the stomach, until the last trace of chyme has been evacuated, whether this is very acid, as in constitutional hyperchlorhydria, or actually alkaline, as in constitutional achylia gastrica. In this way chyme is pressed through the still narrow canal into the duodenum at a uniform rate.

#### (b) Achalasia and Spasm of the Pylorus, and the Origin of Hunger Pain.

The presence of an ulcer in the duodenum frequently upsets the normal pyloric mechanism by giving rise to a

protective reflex, which results in the inhibition of the relaxation which should occur as each peristaltic wave approaches the sphincter. This does not happen until the later stages of digestion, as it is only when the gastric contents have become highly acid that they act as a sufficient irritant to the exposed nerve endings in the ulcer to cause reflex pyloric achalasia. The irritation by acid does not itself cause pain, as extreme hyperchlorhydria may occur in healthy people with no indigestion, and hyperchlorhydria is just as marked in patients with duodenal ulcer between their attacks or after the ulcer has healed as in the presence of a severe attack. Moreover, I have poured dilute hydrochloric acid of a strength greater than ever occurs in hyperchlorhydria into the empty stomach of normal people and of patients with ulcer without causing any pain.

The pyloric achalasia caused by a duodenal ulcer is at first intermittent, but after a time it becomes almost continuous. Consequently the evacuation of the stomach, which begins with the usual rapidity characteristic of the hypertonic gastric diathesis, in the absence of which a duodenal ulcer rarely if ever develops, becomes abnormally slow in the later stages of digestion. After a time the stasis becomes more marked owing to fatigue of the weakened muscular coat of the stomach, intervals of complete inertia alternating with periods of great peristaltic activity. At the same time the tone of the pyloric vestibule begins to give way, the resulting dilatation to the right of the middle line being in striking contrast with the hypertonic condition of the rest of the stomach, but later still the whole of the stomach becomes dilated. The dilatation and ptosis which may therefore occur in chronic duodenal ulcer are secondary, and are due to the loss of tone and delayed evacuation caused by the pyloric achalasia. If the stomach had been examined at any earlier stage, hypertonus and rapid evacuation would have been found, and these characteristics of the hypersthenic stomach gradually return under successful medical treatment.

The secondary delay and dilatation I have described as a sequel of achalasia have often been erroneously regarded as the result of pylorospasm. Although there is no doubt that in the early stages achalasia accounts for everything, when the inflammation round an active duodenal ulcer invades the pyloric canal spasm of the sphincter may actually occur. During periods of active peristalsis, when the x rays show that nothing is passing through the pylorus, it is still possible to squeeze some of the opaque meal into the duodenum by pressure on the stomach so long as the obstruction is due simply to achalasia. But sometimes nothing can be pressed through; in all probability spasm is then present.

It is important to remember that other conditions give rise to similar disturbances in the functional activity of the pylorus, so that the recognition of these disturbances does not by any means prove that a duodenal ulcer is present. The most common is a gastric ulcer, especially if it is situated in the near neighbourhood of the pylorus. But even a lesser curvature ulcer, situated a considerable distance away, occasionally produces so much disturbance in the activity of the pyloric sphincter that considerable stasis results and pyloric obstruction may be simulated. Disease of the gall bladder, and much less frequently chronic appendicitis, may give rise to reflex achalasia. The disturbances in gastric digestion which result are indistinguishable from those caused by achalasia secondary to a duodenal or gastric ulcer. These clinical facts correspond with the results of the experiments of Carlson and Litt, which showed that stimulation of any sensory visceral nerves may increase the contraction of the pylorus.

Observations with the x rays have proved that the hunger pain of duodenal ulcer occurs when the stomach is nearly empty and disappears when evacuation is complete. This corresponds with the only time that peristalsis can increase the pressure within the pyloric vestibule, as each wave then separates the contents of the small part of the stomach distal to it almost completely from the contents of the large part proximal to it. If the pyloric sphincter relaxes, the pressure spends itself in evacuating part of the chyme into the duodenum, the rest passing back as an axial reflux

stream (Fig. 5, A). But if the sphincter remains closed owing to the achalasia caused by the irritation of the ulcer by the very acid gastric contents two or three hours after a meal, it can only spend itself to a slight extent dynamically

FIG. 5.—Section through pyloric vestibule (P.V.) and duodenal bulb (B) in normal man (A), and in a patient with a duodenal ulcer (B), showing how pain is caused in the latter by pyloric achalasia. P.V., Pyloric vestibule; B, Bulb; P.S., Pyloric sphincter (P.S.). S, Spasm in bulb caused by ulcer.

by producing an exceptionally active axial reflux stream (Fig. 5, B). Consequently the tension on the muscular coat of the extreme pyloric end of the vestibule is greatly increased. This is the actual cause of pain, the rise in tension on the individual muscle fibres being the adequate stimulus required to produce the afferent nervous impulse, which calls forth the sensation of pain as well as the corresponding segment of the rectus abdominis muscle. Our investigations several years ago proved that the mucous membrane of the alimentary canal is insensitive to tactile, thermal, and painful stimuli; that neither the normal mucous membrane nor the surface of an ulcer is sensitive to hydrochloric acid of a strength greater than that ever present in the stomach, either in health or disease; and that tension in the muscular coat is the sole cause of the sense of fullness and, when it is sufficiently intense, of the sense of pain.

The conditions responsible for the occurrence of achalasia of the pylorus, together with the fact that the tension in the vestibule can only be increased by peristaltic waves when the bulk of the gastric contents is very small, account for all the distinguishing features of the hunger pain of duodenal ulcer. They explain why it begins when the stomach is nearly empty, but differs from simple hunger in ceasing when evacuation is complete, and why relief is obtained by vomiting, and by all kinds of food or drink, which increase the bulk of the gastric contents and at the same time reduce the acidity of the gastric contents and so more or less overcome the achalasia. Sodium bicarbonate not only acts in both these ways, the evolution of carbon dioxide increasing the bulk of the gastric contents and the neutralization of hydrochloric acid overcoming the achalasia, but the sudden rise in the general intragastric pressure caused by the evolution of carbon dioxide at the same time stimulates the whole stomach to contract: the consequent further rise in intragastric pressure overcomes the resistance offered by the unrelaxed but not abnormally contracted pyloric sphincter, and forces some of the gastric contents into the duodenum. Simultaneously gas is forced through the cardia into the oesophagus, from which it escapes by belching. The pressure in the pyloric vestibule is thus relieved and the pain disappears. Many patients, not realizing that the gas has been produced by the action of the acid on the alkali, regard their relief as due to the sodium bicarbonate making it in some way possible for them to get rid of an accumulation of wind.

Other alkalis relieve the pain less completely and less rapidly, though they may neutralize the acid just as efficiently. In the case of magnesium oxide this is because no gas is evolved, and in the case of bismuth carbonate the carbon dioxide is liberated so slowly that it dissolves in the gastric contents as soon as it forms, so that there is no rise in intragastric pressure and no belching occurs.

When air is swallowed it acts in the same way as the gas given off by the action of acid on sodium bicarbonate. The patient misinterprets his discomfort and thinks it is due to flatulence. The repeated attempts he makes to bring up wind only lead to aerophagy. The sudden rise in intragastric pressure caused by the rapid swallowing of air stimulates the stomach to contract; this results in the noisy belching of air and the simultaneous expulsion of

chyme into the duodenum, as Meunier<sup>14</sup> has demonstrated by actual observations with the x rays. The relief that aerophagists always claim to get, which would otherwise be inexplicable, is in this way explained.

When pylorospasm is present it acts in exactly the same way as achalasia, as even extreme spasm of a sphincter does not by itself cause pain, as the tension on the muscle fibres themselves is the same whether they are contracted and short or relaxed and long.

When a gastric ulcer or disease of the gall bladder causes pyloric achalasia the pain produced is identical in character with that of duodenal ulcer. As the exciting cause is different, the time relations, the factors which give relief, and the history of the attacks are generally distinctive. These characteristics depend not on the way the pain originates, which is the same in each case, but on the different ways in which the achalasia of the pylorus is induced.

#### (c) Symptoms of Pyloric Obstruction caused by Achalasia of the Pylorus.

A year ago a man of 53 came under our observation with an eight years' history of recurrent pyloric obstruction; the pain and very severe vomiting always subsided with a diet of small dry meals. When his abdomen was watched after taking an ordinary mixed meal, the stomach was seen and felt to stand out from the surface of the abdomen as a firm mass, along which passed very powerful peristaltic waves. The evidence of pyloric obstruction seemed so clear that I asked Mr. Clayton-Greene to operate, although a previous exploration had revealed nothing abnormal. No organic disease was found, and the pylorus appeared to be perfectly healthy, but the wall of the stomach was definitely hypertrophied. In view of the absence of obstruction nothing was done, and the patient has remained perfectly well ever since by keeping strictly to small dry meals. It seems probable that this was a case of achalasia of the pylorus, and that if the dietetic treatment had not proved successful, a pyloroplasty would have given relief. It is, of course, a surgical law that no operation should be performed on the stomach in the absence of organic disease, but I think that the very rare cases like the one I have described, in which the clinical and radiological evidence shows that pyloric obstruction is present either continuously or intermittently, the question of pyloroplasty deserves consideration if careful dieting fails to give relief.

#### (d) Hypertrophic Pyloric Stenosis of Infants.

The pyloric obstruction present in the hypertrophic stenosis of infants, whatever may be its cause, results in abnormally vigorous peristalsis, and this leads to hypertrophy of the muscular coat of the stomach, particularly at the pyloric end, where the waves attain their greatest strength. The obstruction is primarily functional, as many, quite typical cases, in which definite hypertrophy of the sphincter has been recognized by palpation, have been cured completely by lavage and dieting, so that it is clear that the hypertrophy itself is not the cause of the obstruction. The obstruction must therefore be due either to achalasia or spasm of the pyloric sphincter. If achalasia were the cause, the violent peristalsis and the contractions of the stomach which can give rise to projectile vomiting would be sufficient to overcome it, and pressure over the stomach, when visualized with the x rays after an opaque meal, would cause some of the chyme to pass through into the duodenum, but this does not in fact occur. It is clear that the obstruction is due to something which produces a much more powerful resistance than simple absence of relaxation. The only possible explanation is spasm. If, as I believe, John Thomson is correct in regarding the spasm as primary, this would explain the development of hypertrophy of the sphincter, and it is the spasm which is overcome by successful medical treatment.

The cause of the spasm, which apparently originates at birth, as the symptoms often begin in the first week of life, and always within the first two months, is still quite obscure. It is always associated with hyperchlorhydria, and the condition is several times more common in boys than in girls. It therefore seems possible that the tendency to spasm of the pylorus is the expression in an extremely

exaggerated form of the constitutional condition which I have called the hypersthenic gastric diathesis, which manifests itself by hypertonus, hyperperistalsis, and hyperchlorhydria, and occurs much more commonly in men than in women. The diathesis is often present in several members of a family; this would explain the rare instances in which two and even three or four members of the same family have hypertrophic pyloric stenosis.

#### THE ILEO-CAECAL SPHINCTER.

##### (a) Anatomy and Physiology.

The valve-like structure which separates the ileum from the caecum was discovered in 1579 by Caspar Bauhin, who believed that it allowed the free passage of the contents of the ileum into the caecum, but prevented regurgitation in the opposite direction.

Though Mason Good<sup>15</sup> in 1822 described the ileo-caecal junction as a muscular structure, the function of which

was "to moderate the flow" from the small intestine into the colon and "to prohibit a regurgitation of the faeces" from the caecum into the ileum, his work was completely forgotten, and the separation of the contents of the small from those of the large intestine was still universally regarded as a result of the mechanical action of Bauhin's "valve" until 1903, when Keith<sup>16</sup> clearly demonstrated the existence of a strong ileo-caecal sphincter. His observations, and the more recent ones of Rutherford,<sup>16</sup> show that the sphincter is formed by the fusion of the circular and longitudinal fibres of the

FIG. 6.—Section through end of ileum and caecum (after Spalteholz) to show structure of ileo-caecal sphincter. (After Rutherford.) I, ileum; C, caecum; A.C., ascending colon; I.C.S., ileo-caecal sphincter; A, appendix.

end of the ileum and those of the adjoining caecum, with the addition of some independent specialized circular fibres at its apex (Fig. 6).

Rutherford in 1914 made some important observations on the human ileo-caecal sphincter through a large caecal fistula. He found that it formed a smooth, scarlet, hemispherical papilla, about 1.8 cm. in diameter, which projected about 1 cm. above the pink and folded mucous membrane of the caecum (Fig. 7). The orifice was closed and formed a dimple in the centre of the papilla. During periods of activity a peristaltic wave could be seen through the relaxed wall of the caecum to traverse the end of the ileum at regular intervals. When it reached the caecum the orifice opened owing to relaxation of the sphincter, which at the same time caused the papilla to become larger and less prominent.

FIG. 7.—Appearance of papilla formed by the ileo-caecal sphincter in man, as seen from the interior of the caecum during life. (After Rutherford.)

About a drachm of fluid faeces, sometimes mixed with flatus, emerged. The sphincter then closed, and became again more firm and prominent. No sign of the fraenum described by anatomists was ever observed.

In 1904 Elliott<sup>17</sup> had demonstrated that the tone of the sphincter depended upon its sympathetic nerve supply, as section of the splanchnic nerves was followed by its permanent relaxation, with the result that the contents of the small and large intestines mixed freely with each other. On the other hand, direct stimulation of these nerves, or indirect stimulation by means of adrenaline, caused the sphincter to contract tightly at the same time as the movements of the rest of the intestine were inhibited. Stimulation of the vagi and pelvic nerves had no effect. Keith<sup>16</sup> has found that nodal tissue forming Auerbach's plexus is as remarkably developed at the ileo-caecal sphincter as it is at the cardia.

The main function of the ileo-caecal sphincter is to prevent the contents of the ileum passing too rapidly into the caecum. Alan Newton of Melbourne and I<sup>18</sup> found with the x rays that the barium-containing chyme reaches the end of the ileum an hour or more before any appreciable quantity enters the caecum, and that the ileum is often still full four or five hours after the last traces of barium have left the stomach. Consequently an accumulation of chyme occurs in the terminal ileum, where it actually remains for a greater period than in the stomach. During the whole of this time active segmentation, which leads to thorough churning of its contents, can be seen in the last few inches of the ileum, but there is very little peristalsis. It is evident that the ileo-caecal sphincter has exactly the same effect on the contents of the terminal ileum as the pyloric sphincter has on the contents of the stomach; it controls the onward passage of the chyme so that sufficient time may elapse for digestion and absorption of the food to be complete. This physiological ileal stasis is so well regulated that the chyme which reaches the caecum contains only very small quantities of nutrient material in solution.

The ileo-caecal sphincter relaxes each time a peristaltic wave passes down the last few inches of the ileum. Though these waves begin a short time after the chyme first reaches the ileo-caecal junction, they are at first very infrequent. As a result of the gastro-ileal reflex, which I first described fifteen years ago, active peristalsis occurs in the extreme end of the ileum, the sphincter relaxes, and chyme enters the caecum whenever food enters the stomach.

It was at one time thought that the ileo-caecal sphincter had an important function to perform in preventing the regurgitation of faeces from the colon into the ileum. But we now know that under normal conditions there is no anti-peristalsis in the proximal part of the colon, so that there is never any tendency for the contents of the caecum to pass back into the ileum. When, however, retrograde movement of the contents of the colon occurs in cases of obstruction, and after distension of the bowel with an enema, the sphincter is not capable of withstanding any considerable degree of pressure from the side of the colon, as the x rays show that part of an opaque enema given to normal individuals at no greater pressure than eighteen inches of water frequently passes from the caecum into the end of the ileum.

##### (b) Pathological Ileal Stasis.

So many ill results have been ascribed to ileal stasis that one requires a certain amount of courage to express a doubt as to whether it is ever of the slightest importance, except in cases of organic obstruction near the ileo-caecal junction due to a growth, tuberculosis, or definite adhesions the sequel of acute appendicitis. But in my experience intestinal poisoning is due far more frequently to the artificial diarrhoea produced by aperients than to intestinal stasis; the only form of intestinal stasis which gives rise to symptoms is that involving the caecum and ascending colon; and, if in exceptional cases this is associated with well marked ileal stasis, it is the colonic rather than the ileal stasis which is the more important. Cases of true small intestine poisoning, such as the streptococcal infection of the duodenum constantly present in Addison's anaemia, are secondary to gastric achylia and not to colon infection, and they are never associated with ileal stasis.

When ileal stasis occurs in the absence of organic obstruction, it is generally due to reflex achalasia of the ileo-caecal sphincter caused by chronic appendicitis, exactly corresponding to pyloric achalasia in duodenal ulcer. Kinks of the terminal ileum are doubtless interesting developmentally, but they are of no clinical importance, as they never lead to sufficient narrowing of the lumen to obstruct the passage of the fluid contents of the ileum, for peristalsis is wonderfully adapted for propelling the contents of a muscular tube round bends, whether they are normal flexures or so-called kinks. If a kink caused true obstruction it would not be seen with the x rays, because the distal segment would be empty. The so-called "controlling appendix" is never the direct cause of ileal obstruction; it may control the passage of faeces into the caecum by causing achalasia of the ileo-caecal sphincter, but only if it is chronically inflamed.

## THE PELVI-RECTAL AND ANAL SPHINCTERS.

## (a) Anatomy and Physiology.

In his *New Views of the Process of Defecation*, published in 1833, James O'Beirne drew attention to the important function of the flexure, formed where the morable pelvic colon joins the fixed rectum at an acute angle, which is best described, I think, as the pelvi-rectal flexure.

FIG. 8.—Frozen section through pelvi-rectal flexure, showing thickening of circular muscle layer forming termination of pelvi-rectal sphincter (P.R.S.). P.E., Pelvic colon; R., rectum; P.P., peritoneum; S., sacrum. (After Symington.)

O'Beirne from the results of digital examination of the rectum and of experiments with a rectal tube, that under normal conditions the faeces do not pass beyond the pelvi-rectal flexure, but collect in the pelvic colon until immediately before defaecation. I believe that this is due to the presence of a true pelvi-rectal sphincter, which resembles the cardiac sphincter rather than the pyloric and anal sphincters in depending upon its postural tone being sufficiently great to obliterate its lumen rather than upon any considerable development of a special band of circular muscle fibres. W. J. Mayo<sup>10</sup> has pointed out that the folds of mucous membrana are disposed in a longitudinal direction in the last two inches of the pelvic colon, in contrast with their circular arrangement in the remaining portion; this suggests that the lumen of the last two inches is normally obliterated owing to a sphincter action of the circular muscle fibres analogous to what I have described in connexion with the abdominal portion of the oesophagus (Fig. 9). The sphincter's action is considerably assisted by

FIG. 9.—Diagrammatic section through last 3 inches of pelvic colon, rectum, and anal canal, showing pelvi-rectal sphincter (P.R.S.) with its longitudinal folds, ending at pelvi-rectal flexure (P.R.F.). A.A., Ampulla recti; A.C., anal canal, surrounded by internal sphincter ani (I.S.) and external sphincter ani (E.S.), and strengthened by levator ani muscles (L.M.). R., rectum; N., the three folds of Houston.

the very acute angle formed where the dependent pelvic colon joins the fixed rectum, especially in the erect position. The gastro-colic reflex which occurs when food enters the stomach results after breakfast in a wave of peristalsis passing along the distal part of the large intestine; the obstruction at the pelvi-rectal flexure is overcome, presumably as a result of relaxation of the sphincter, and the pelvic colon empties itself into the rectum. The sudden distension of the muscular walls of the rectum gives rise to a sensation in the perineum which is recognized as the call to defaecation. The observations recorded in my Gonstonian

## (b) Hirschsprung's Disease, the Megacolon of Adults, and Achalasia of the Pelvi-Rectal and Anal Sphincters.

The condition described in 1835 by Hirschsprung of Copenhagen, in which children, most often boys, from early infancy become progressively more constipated owing to the failure of the dilated and hypertrophied colon to empty itself, is much less rare than was at first believed. Several cases generally end fatally before the age of 8, but investigations with the x rays and the sigmoidoscope show that patients suffering from a milder form of the condition may grow up in sufficiently good health to lead normally active lives. One of my patients was, indeed, an Oxford rowing blue. It is remarkable how greatly dilated the colon may be without causing any protrusion of the abdominal wall, and how, as in three of my cases, a hugely dilated loop of pelvic colon may actually be situated above the liver without giving rise to any symptoms. There does not appear to be any clear distinction between the cases of megacolon in adults, who complain of nothing beyond a moderate degree of constipation, and the fatal cases of Hirschsprung's disease in young children. In the former the hypertrophy of its muscular coat has made it possible for the colon to overcome the obstruction at the pelvi-rectal flexure or anal canal sufficiently to prevent the accumulation of enough flatus and faeces to cause a dangerous degree of dilatation. In the latter the hypertrophy has not kept pace with the dilatation, and colon failure—analogous to heart failure in mitral stenosis—finally occurs with fatal results.

FIG. 10.—Composite drawing of a megacolon, due to anal achalasia in a woman of 43, made from radiographic observations after an opaque meal and an opaque enema. C, caecum; A.C., ascending colon; R.C., transverse colon; ascending limb of which passes to P.R., splenic flexure, outside P.R., descending colon, which merges into the hugely dilated pelvic colon, P.C.; this reaches above the liver, which is shown shaded, and finally joins R., the dilated rectum.

The lower limit of the dilated colon is with equal frequency at the pelvi-rectal flexure and at the sphincter ani. It has always been recognized that no organic obstruction is present in these cases, although the violent peristaltic contractions of the colon which can be seen through the thin abdominal wall and the hypertrophy of the muscular coat which results from this show that some functional obstruction must be present. The obstruction must, I believe, be due, in the cases in which the dilatation begins at the pelvi-rectal flexure, to achalasia of the pelvi-rectal sphincter, when, at the commencement of defaecation, a peristaltic wave passes down the pelvic colon and reaches the flexure in the process of emptying the pelvic colon into the rectum. In the cases in which the rectum is dilated a similar condition of achalasia affects the sphincter ani, which fails to relax when the peristaltic wave which should evacuate the rectum reaches it. In both varieties the condition of the colon is strictly comparable to the dilated and hypertrophied oesophagus, which, I have shown, is caused by achalasia of the cardia.

Anal achalasia never calls for surgery. It is quite easy to keep the colon empty by lavage, as a tube can always be readily passed through the sphincter. This should be done every day at first, then every two or three days, and finally, only if an accumulation appears to be forming. An attempt should be made at the outset to diminish the resistance offered by the unrelaxed anal sphincter by forcibly dilating it, in spite of the fact that it is never found to offer more than the normal resistance when a finger is inserted into the rectum, and that no hypertrophy of the sphincter is ever present, in contrast with that which follows the long-continued anal spasm caused by a chronic anal ulcer.

In pelvi-rectal achalasia also the colon must be emptied by daily lavage. But in some cases the water which reaches the dilated pelvic colon remains in it, and nothing is evacuated. An attempt should then be made, with the patient in the knee-elbow position, to manipulate a tube, through which water is running, past the pelvi-rectal

flexure. If this does not succeed, a sigmoidoscope must be passed and the rubber tube introduced through it. If this also fails, the abdomen must be opened. On pulling the distended colon upwards, a tube can be passed into it from the anus, and the bowel is then emptied. After this has been done it may be possible to pass the tube daily in the manner already described, as the obstruction originally caused by the pelvi-rectal achalasia is always increased by the kink produced by the greatly dilated pelvic colon where it joins the undilated rectum. If, however, this eventually becomes impossible, an anastomosis should be made between the undistended rectum and the terminal ileum, or, preferably, the under surface of the extreme end of the pelvic colon. It is, however, exceedingly difficult to do this, and it may even be quite impossible owing to the small size of the rectum and to its situation deep in the pelvis. In such cases nothing short of excision of the whole of the dilated colon is likely to give relief.

## RADIOLOGICAL EXAMINATION IN ORGANIC DISEASES OF THE COLON: THE OPAQUE ENEMA METHOD.

BY

S. GILBERT SCOTT, M.R.C.S., L.R.C.P.,  
RADIOLOGIST TO THE LONDON HOSPITAL.

THE clinical evidence presented in most cases of colonic disease is meagre, variable, and often unreliable.

The sigmoidoscope will give direct evidence if the lesion is within its reach, but unfortunately this does not often happen. At its best, this form of examination only covers the last few inches of the colon itself. On account of the low malignancy of the majority of cancerous growths of the colon, their early diagnosis is of great importance, and any method of examination whereby direct evidence may be obtained before operation is valuable.

The radiological examination, using some opaque fluid as the medium, if carried out correctly, will give reliable and definite information in diagnosing the presence of an organic lesion of the colon. It is, of course, not always possible to distinguish between certain types of lesion, such as tuberculosis and carcinoma of the gut, but the fact remains that by a radiological examination the disease may be detected and located, which is of considerable surgical importance.

The radiological methods at command are: (1) the opaque meal given by the mouth and followed through to the anus—at one time the only routine in use, and (2) the opaque enema. Both methods have their advocates, but those who have had the opportunity of examining a number of colonic cases will have no hesitation in deciding which of the two is the more reliable. I entertain no doubt that the opaque enema is the only practical way of making a detailed examination of the lumen of the large gut. It is, in fact, as valuable as the opaque meal in the detection of gastric lesions.

Advocates of the opaque meal examination may say that a colonic obstruction can be detected in this way, but this is certainly not correct in a number of mechanical obstructions due to new growths. At its best it is unreliable; I have seen cases of colonic carcinoma where there has been no delay or obstruction in the passage of the meal from

the mouth to the anus, and yet there has been complete obstruction to the opaque enema. The reason for this has not been satisfactorily explained, but the fact remains.

The two chief disadvantages attached to the opaque meal method are: (1) That the examination is prolonged; several days, even weeks, may be required before the colon clears itself, and the final result, even then, is unreliable. (2) The second disadvantage is that colonic haustiation or segmentation is very marked, the uneven distribution of the opaque salt rendering a detailed examination almost impossible.

The advantages of the opaque enema are that the examination is rapid, the whole gut being filled from rectum to caecum in a few minutes; that the almost complete absence of haustiation renders small filling defects of the lumen easily detectable; and that if the enema is properly administered there is practically no discomfort to the patient.

The disadvantages are few and insignificant, compared with the data obtainable. My colleagues say it is a "messy" job, but except for occasional accidents not a drop of the opaque substance used should escape outside the body. Excluding accidents, a "mess" is indicative of faulty technique. The alleged discomfort for the patient has already been dealt with. It is a curious fact that the large majority of patients display no concern whatever, even when the colon is fully distended from rectum to caecum. This is possibly due to the preparatory wash-outs.

## METHOD OF EXAMINATION.

Unless the opaque enema examination is carried out with careful attention to technical details it may lead to serious errors in diagnosis, discomfort to the patient, as well as to the operator, and its value as a diagnostic agent will be lessened.

## Preparation of the Patient.

As our object is to inject a foreign substance in an organ which normally is already full, a clearance of its contents is essential. In other words, the colon must be free of faeces. Anyone who has seen the opaque fluid obstructed by a hard mass of faeces will realize the importance of efficient clearance, as its appearance is remarkably like the obstruction of a new growth.

Castor oil is the most reliable aperient. This should be administered at least thirty-six hours before the examination, for unless the effect has passed off by the time operations begin there is a risk of the opaque enema being returned. Light diet follows the aperient. A plain water enema is administered the night before and a second on the morning of the examination. This procedure will ensure an empty colon. The medical man in charge of the case should fully realize the importance of this preliminary preparation indicated by the radiologist. Serious errors in diagnosis may otherwise be made.

## Apparatus.

A douche-can of the usual pattern, in which the outlet is about an inch from the bottom, is the most suitable. Any sediment that may collect can thus settle down without blocking the tube. I have tried several other patterns, but this type is the best. About four feet of thick-walled rubber tubing is attached to the can and to the end a Higginson's syringe is added, the valves of the syringe being removed, as they would soon become blocked. The use of the bulb of the syringe will be discussed later. The acorn-shaped rectal nozzle made in metal will be found to be the most suitable. It throws a shadow, so that its correct position can be verified before the injection takes place, and its shape renders it less liable to slip out.

The douche-can, which is placed about two feet above the patient, is now filled three-quarters full ( $1\frac{1}{2}$  pints) with the barium emulsion (Ranul No. 3) warmed to body temperature. The clip which is placed on the tube to control the flow is released and the emulsion run up to the nozzle; this excludes the air. The clip is now closed. The end of the nozzle only is smeared with a small quantity of vaseline. If the whole is lubricated there is a tendency for it to slip out during the injection. The patient, suitably attired, lies on his back, with a towel under the buttocks and a pad of cotton-wool under the sacrum. With nervous patients,

or where there has been any difficulty in retaining the preparatory wash-outs, it is as well to place a mackintosh under the towel. This, however, is not often necessary.

The nozzle should be inserted very gently, care being taken to see that it is pushed well home. Before commencing the flow of barium emulsion a glance is taken on the screen to ascertain whether the position of the nozzle is correct. The tip should be on a level with, or above the level of, the symphysis pubis, never below. This procedure will prevent accidental ejection, but will not necessarily prevent an accident that once happened to me when the nozzle was inserted into the vagina by an inexperienced nurse. The pad of wool, which is already in position under the sacrum, is now tucked firmly round the enema tube. This will keep it in position and incidentally prevent leakage. The clip can now be released and the filling of the colon commenced. The patient is instructed to say whether any pain or discomfort is felt during the examination. Very few experience any uncomfortable symptoms whatever if the injection is carried out gently and without haste.

The S-shaped pelvic colon quickly fills. A short delay may occur at the junction of the sigmoid and descending colon, due to a sphincteric action. Some delay may also be noted at the splenic flexure. In a normal case the colon should be completely filled in about five to eight minutes. In quite a number of cases the enema is seen to pass right through the ileo-caecal valve and occasionally the appendix itself is filled.

Pressure on the ball of the Higginson syringe is found to be of considerable value during the injection. Not only can the flow be hastened, but, what is still more important, any alteration in the colonic tension is at once conveyed to the hand. Experience enables one to become very sensitive to any alteration or variation of this colonic tension—so much so that it becomes possible to distinguish between the increased tension caused by muscular contraction, such as peristalsis or spasm, and that of obstruction by a new growth. In dealing with a difficult patient it is a wise precaution to glance occasionally at the anal region on the screen; a leakage of the emulsion will in this way be at once detected before any quantity escapes.

As soon as the caecum is seen to be fully filled the flow is shut off, the nozzle removed, and the pad of cotton-wool, used to prevent leakage, wrapped round it on removal. If this is done not a drop of the emulsion should escape during the examination.

Systematic examination of each section of the gut is now carried out, careful palpation being used where possible. It will be found necessary to turn the patient in various directions to obtain a clear view of the coils lying in the pelvis as well as when examining the flexures. In some cases even this procedure will not throw the pelvic coils clear of one another. I overcome this difficulty by injecting a few ounces of warm water; this dilutes the contents of the lower bowel, rendering the shadow less dense, and one coil can in this way be seen through the other.

Radiographs may be taken to illustrate any abnormal condition, but they rarely give any more information than what has already been obtained from the screen examination, where palpation has been utilized.

The patient is now allowed to discharge the colonic contents, and this is followed by a final *fluoroscopic* examination, which is specially important when there is a question of diverticulitis.

These technical details have been fully dismissed as the success of the examination and the attainment of its full diagnostic value depend on their observance.

#### MORPHOLOGY AND TOPOGRAPHY OF THE COLON.

##### Tone.

A considerable variation in tone occurs in the colon, similar to that seen in the rest of the intestinal tract. This is determined to a great extent by the mental attitude of the patient. Apprehension, for instance, may be present in this form of examination. The fear of being unable to retain the enema weighs heavily on some patients; the result, especially noticeable in females, is an abnormal increase in the general tone, amounting even to spasticity of

the colon during the examination. These cases require careful handling if the examination is to be carried to a successful termination.

I have already drawn attention to this variation of tone in respect to the stomach—it alters day by day, almost hour by hour. A hypertonic stomach to-day, in fact, may be a hypotonic stomach to-morrow, and this is equally true of the colon. It is noticeable that this tendency to hypertonicity occurs more frequently in the descending section. If it is purely a transitory condition the contracted lumen will relax before the termination of the examination, showing a fully filled gut. If of a more permanent nature, as is sometimes seen in spastic constipation, no relaxation takes place. A local spasm is of frequent occurrence, but the smooth symmetrical constriction, not infrequently altering its position, should not give rise to much difficulty in diagnosis. This condition may be found in any section.

##### Haustration.

One of the advantages of the opaque enema examination is that it does away with colonic haustration. The colon is filled out to its fullest extent like the inner tube of a tyre, any defect in filling being thus readily detected. This absence of haustration, however, is not necessarily present during the whole of the examination. Each section should be carefully examined, using palpation, while it is free of segmentation. Even if it is somewhat persistent, as may occasionally happen, the fact that it is symmetrical and not unevenly broken up, as is seen when an opaque meal has been administered, will render the examination satisfactory and accurate.

##### Topography.

Owing to the large variation in the position of a normal large gut, it is impossible to give any reliable landmarks. Probably the rectum and splenic flexure are the most constant in position, the transverse colon, hepatic flexure, and caecum being the most variable.

It may be of advantage here to describe the filling of a normal colon. The fluid rapidly fills the S-shaped pelvic colon, a short delay occurring at the sigmoid sphincter, as I call it. Although there is some doubt as to the existence of a muscular sphincter at the junction of the pelvic colon and sigmoid, radiologically there is without doubt a narrowing of this junction—usually most pronounced at the commencement of the injection; in any case a definite delay in the flow may be anticipated here. The descending colon readily fills. This is the narrowest portion of the colon.

The splenic flexure fills in its turn. This is usually high up under the costal cartilage; a deep breath, however, will bring it down within reach of the palpating hand. One is apt to get the impression that there is delay in the filling of this flexure. On investigation, however, this will not be found correct. The explanation is that this loop is being viewed end on, and also that the shadows of the two limits of the loop overlap one another, the column of fluid in the proximal side not getting clear of the distal limb for some six inches or more below the upper limit of the flexure. This condition can be verified by palpation.

The fluid now readily flows across the transverse colon as far as the ascending section; the caecum takes somewhat longer to fill completely. Early carcinomata of the caecum will be missed unless care is taken to fill it as completely as possible.

Frequently the fluid passes into the ileum and even into the appendix. This flowing into the ileum has hitherto been attributed to an incompetent ileo-caecal valve. I do not, however, think that this is correct in all cases. The valve was not designed to stop the back flow of a fluid such as is used in this examination.

##### Detailed Examination of the Fully Filled Colon.

Many puzzling defects will be noted during the process of filling the colon. The explanation is probably the result of spasm or local air-locks. In any case, it is wise not to give an opinion on a case unless the colon is completely filled. The caecum should be seen fully filled before commencing a detailed examination. The inflow, of course,

must be carefully watched, as much valuable information will probably be obtained during the passage of the opaque fluid. Many a puzzling defect noted while the colon is filling will have disappeared by the time the colon is filled to its fullest extent.

#### DEVIATION FROM THE NORMAL DUE TO CAUSES OTHER THAN ORGANIC DISEASE.

##### *Dilated Rectum.*

The pelvic section may be dilatable to an unusual degree. This may occur in cases of constipation. The dilatation, which may be considerable, is limited to the rectum and pelvic colon. In these cases there appears to be a complete loss of muscular tone, and nerve impulses are probably no longer sent out from this section, even when grossly overloaded. The whole colonic mechanism is thus put out of gear, and troublesome constipation may ensue.

##### *Extra Loops.*

The more common sites for extra loops are as follows:

1. Redundant sigmoid.
2. Descending colon—about the level of the crest of the ileum.
3. Both flexures.
4. Ascending section.

It would be an interesting study in comparative anatomy to ascertain whether any of these loops correspond to analogous conditions in the lower animals. In other words, are they of ancestral origin?

No special description is needed, except possibly of the redundant sigmoid, which occurs more frequently than the others. This extra loop may reach remarkable dimensions, extending up as far as the transverse section. Although congenital—possibly of ancestral origin—this extra looping does not cause symptoms, although I sometimes wonder whether it might not do so in some circumstances, as a number of patients in whom this condition is found, and who present themselves for this examination, complain of vague abdominal symptoms. No apparent obstruction, however, is noticeable in such cases.

While the degree of looping is variable, the indication of its presence is constant in position; for instead of the column of fluid following an outward direction after filling the pelvic colon, it is seen creeping upwards from the upper limit of the S, following the loop round and joining the descending section at its normal level.

##### *Jacksonian Membrane.*

This is a rare condition, due to the presence of a membrane in the region of the hepatic flexure. The membrane is stretched over the gut, flattening it out to a greater or lesser extent. It may be present without giving rise to symptoms. The smooth outline of a narrowed section of the gut in the region of the hepatic flexure, causing no great degree of obstruction, should easily differentiate it from a new growth.

##### *Enteroptosis.*

Only a general description will be given of the part played by the colon in this baffling condition. Considering its extreme frequency, it is surprising that not more is known of its cause. Let it be clearly understood that radiologists can only state the position of the various sections, the muscular tone, and the rate at which the contents pass through. The deductions must be left to the physician. It is possible to have an extreme degree of enteroptosis without any symptoms. In fact, the intestinal tract may be functioning perfectly normally, in spite of its low position. Therefore, the position of the organs is not necessarily the deciding factor in these cases.

There is another point. At what level does enteroptosis begin? To some radiologists every case examined has some degree of ptosis of the transverse colon; to others it is the hepatic flexure which offends. The whole subject needs revision—at any rate from the radiological point of view. We do not yet know to an inch on what level our organs

should be. I hope to return to this subject at some future time. Briefly, colonic ptosis may be classified as follows:

1. Caecal—so-called pelvic caecum.
2. Right half of colon down (single flexure).
3. Splenic "drag," due to the splenic flexure remaining high up in its normal position, thus taking the weight of a loaded right half of colon. This frequently gives rise to pain under the left costal margin and may be diagnosed as of gastric origin.
4. Ptosis of both flexures with, of course, the transverse colon.

The examination of suspected cases of enteroptosis by the opaque enema has certain advantages over the meal. In the first place, there is a saving of time, as the whole colon can be examined at one sitting. Several days may otherwise be necessary before the meal reaches its journey's end. Secondly, the functioning properties of each section can be more accurately gauged.

It is, of course, necessary to examine the patient in the upright and recumbent positions, palpation being used to see if it is possible to manipulate the gut into its normal position. In addition, an opaque meal is given to ascertain the position of the stomach to the colon.

If the patient now attempts to evacuate the bowel, a second examination will determine and locate the residue, giving an indication of its emptying powers.

##### *Adhesions.*

Fixation of sections of the gut that should normally be free, with or without narrowing of the lumen, indicates the presence of adhesions. Adhesions of the large gut are rare, and care should be exercised in their diagnosis, as frequently there is apparent fixation owing to muscular contraction of the abdominal wall preventing efficient palpation. The caecum is often difficult to manipulate on account of its low position in the pelvis. Raising of the buttocks and deep respiration will cause it to move up if not fixed by adhesions.

##### *Determining the Relation of Abdominal Tumours to the Colon.*

A tumour may be felt through the abdominal wall. Its relation to the large gut may be of considerable surgical importance. This is easily ascertained by rendering the colon visible by an opaque enema. Occasionally the tumour will be found to be so closely connected with it as even to alter its lumen, but unless this alteration gives the irregular stricture characteristic of a new growth it must be considered as a tumour originating outside the gut, involving it only as a secondary condition. A tumour in the left flank, diagnosed as a growth of the descending colon, was shown by this method to be pressing on the gut, flattening it out, but not part of it. A detailed examination proved the lump to be an enlarged low kidney—a hypernephroma. The surgical value of this information need not be emphasized.

##### *Pressure of Gall Bladder.*

Pressure on the gut in the region of the hepatic flexure of an enlarged gall bladder may sometimes be detected.

##### ORGANIC LESIONS.

The presence of the following pathological conditions can be determined by means of the opaque enema:

1. New growths.
2. Diverticulation.
3. Tuberculosis.
4. Polypus (rectal).
5. Benign tumours—adenoma, fibroma, lipoma.
6. Chronic ulcerative colitis.

##### *New Growths.*

Here the diagnosis is dependent on (a) obstruction, (b) distortion of lumen. In the very early stages, while the growth is small, and before it encircles the whole lumen of the gut, detection is very difficult, unless a section that can be easily manipulated is involved.

While these early new growths are the type most frequently missed by the opaque enema examination, patients rarely come for the examination until the disease is well advanced. In respect to the obstruction resulting

from the presence of a new growth it is of interest to note that the passage of an opaque meal given by the mouth may be quite unobstructed. In other words, there may be no delay whatever and yet the obstruction will be complete to the opaque enema. Various suggestions have been made to account for this phenomenon, but my impression is that a channel through the new growth is moulded—probably into the shape of a funnel—by the onward passage of faeces, a valve-like closure taking place when the enema is administered. In any case, it is rare for a colonic growth to be present without giving rise to definite obstruction to the passage of the opaque enema.

The first indication of this obstruction is the sudden increase in colonic tension—imparted to those who are able to appreciate it—through the rubber ball of the modified Higginson syringe already mentioned. The column of the barium fluid ends abruptly as it comes up against the growth. In other words, it is straight-faced. Gradually a small amount may be enticed through the stricture. Care must be taken at this stage not to use force, otherwise damage may be done or the enema may be returned. Once the emulsion has got through the narrowed section, the extent of the disease can be gauged. The narrowed channel is usually irregular and tortuous, similar to a new oesophageal growth. I smooth in outline, care should be taken to eliminate local spasm; at the same time it must be remembered that in some cases of annular growths the stricture may be smooth, but then it is permanent. Palpation here may be of considerable use, for although no actual tumour can be felt, the rolling of the suspected area of colon from side to side under the fingers will impart a definite sensation of thickening of the wall.

The most difficult section to examine is the pelvic colon and first part of the sigmoid. The coils tend to overlap one another and considerable ingenuity is necessary to disentangle the shadows, especially as palpation is not possible in this portion of the gut. Now, by injecting water, this difficulty may be overcome has already been described. A new growth involving the caecum may be overlooked or a wrong diagnosis of diseased colon may be made, unless care is taken that this portion is fully filled. There is a tendency to what I take to be an air-lock in this region, giving an irregular outline to the caecum. Palpation, however, will help it to fill to its fullest extent, but if this is unsuccessful the object will be achieved by turning the patient on to the face for a few minutes. Dilatation of the distal side of the obstruction is by no means unusual.

As previously mentioned, the opaque enema is the only satisfactory method of detecting the presence of narrowing or distortion of the gut, and the extent of the disease.

#### *Tuberculous Disease.*

Although a rare condition, tuberculous disease may be considered here owing to the fact that it closely resembles a new growth in its radiological appearances.

While tuberculous disease certainly causes narrowing and distortion of the gut, this is usually limited to one side, not involving, as with a new growth, the whole lumen. The proximal half of the colon is commonly implicated. The lesion is usually more extensive and the obstruction is seldom so complete as when caused by a new growth. The history of the case will also assist a correct interpretation of the findings. It is, however, by no means easy to distinguish between these two lesions. Differential diagnosis is also difficult between (a) adhesions, (b) actinomycosis, (c) abscess, and (d) extrinsic tumours.

#### *Colonic Diverticulation.*

This condition is more frequent than is generally supposed, but it does not necessarily give rise to symptoms unless inflammation supervenes. It is by no means uncommon in patients over 45. This pouching or sacculation of the colon is probably the result of some defect in the muscular coat, congenital or acquired. The diagnosis depends on the filling of these diverticula with the opaque fluid, and are either seen as bud-like projections, while the gut is fully distended, or as button-like shadows left behind after evacuation. They may be sessile or pedunculated, and are situated outside the limit of the gut. Examination immediately after evacuation may show a few of these sacculi, but

many more will be detected if the examination is made again in twenty-four hours.

I have found that diverticula may remain filled with the opaque fluid for several weeks after the enema, and this even after vigorous irrigation of the colon. What part diverticula play in intestinal toxæmia has yet to be established, but the fact that they may not be emptied even by repeated washings out of the gut at once raises the question whether some of the cases of chronic infection may not be the result of absorption from these diverticula, adding yet another source of infection to the already long list. Diverticula, in fact, may be looked upon as miniature appendices that may become chronically and occasionally acutely infected. A term is wanted to describe the condition when diverticula are present without inflammatory changes. The term "diverticulitis" implies inflammation. I suggest the term "colonic diverticulation."

In all suspected cases, or where the examination has revealed nothing abnormal, an examination after twenty-four hours is essential. Diverticula usually occur in the descending portion or sigmoid, although they may be found in any section of the colon and occasionally along its whole length. If there has been any inflammatory condition present (diverticulitis) it is rare for the opaque fluid to get into the particular diverticulum involved, as the opening into the gut is usually occluded. Other patent diverticula are, however, as a rule present, indicating the nature of the case. Residue in the colonic haustra should not be mistaken for diverticula.

#### *Benign Tumours.*

These are rare and the radiological differentiation almost impossible. Smooth defects in the outline of the lumen, not characteristic of a malignant tumour, may lead one to suspect the simple nature of the lesion. Polypi will cause a smooth defect if large enough, with little or no obstruction, the shadows cast by the gut in the region being rather mottled in appearance. Multiple adenomata give a similar picture.

#### *Chronic Ulcerative Colitis.*

The element of spasm is the main feature here. This leads to a spastic condition of the colon, usually of the descending portion, giving rise to an extensive narrowing of a considerable part of the gut. In rare cases the opaque fluid can be seen adhering to the ulcer surfaces themselves after evacuation. The presence of diverticula may cause symptoms of colitis, and care should be taken not to overlook this condition.

#### CONCLUSION.

While examination by the opaque enema has been employed for some years, I feel that a more extended use of this method could be made with advantage in this country. But it must be realized that the examination is beset with pitfalls for the unwary.

If careful attention be given to the technical details the method will prove to be rapid and accurate, and to cause minimum discomfort to the patient.

## CONCEALED ACCIDENTAL HAEMORRHAGE

BY

T. H. RICHMOND, O.B.E., M.B., CH.B., F.R.C.S. ED.,  
GYNAECOLOGIST, LONGTON HOSPITAL, STOKER-ON-TRENT.

IN addition to the relative rarity of concealed accidental haemorrhage there are several points in the following case of more than passing interest.

On January 1st, 1924, I was asked by her family doctor to see a well developed woman of 26, who was in the thirty-fifth week of her first pregnancy. Down to eighteen hours before I saw her she had enjoyed good health and the urine had been free from albumin. At 10 p.m. on December 31st, 1923, without any apparent cause she was seized with severe cramp-like pain in the epigastrium. An hour later she became faint and complained of a sensation of great fullness in the abdomen. She was carried to bed, and shortly afterwards felt sick and vomited without gaining any relief. Down to the time when I saw her every attempt at ingestion of food or to raise her head resulted in a recurrence of the faintness and vomiting. The bowels had not acted and she was unable to say if she had passed flatus. There was increased frequency of micturition. While the pain had continued without

intermission from the onset of the attack, she did not think it had differed in character after the end of the first hour. At no time had she any feeling of air hunger.

She lay in a dazed, apathetic condition, and was markedly pale, but of a fawny white rather than the ashy grey colour of secondary anaemia. The pulse was 108 and the temperature 98° F. The abdomen was greatly distended and gave a sensation of hard tenseness. This distension was chiefly localized in the upper segment and passed under the costal margins. No sounds could be heard on auscultation, nor could any movements be recognized on inspection or palpation. The tenderness she complained of could not be described as severe. No blood was found in the vagina, nor was there any staining of her clothing. The os was dilated (2 cm.), with distended membranes bulging through. Concealed accidental haemorrhage was diagnosed and Caesarean section recommended. This her husband agreed to, but requested that the uterus should be preserved if found possible. She was removed to Longton Hospital.

At 7.30 p.m. on January 1st, 1924, under a general anaesthetic, the abdomen was opened through a mid-line incision extending from 1 inch above the umbilicus to 1 inch above the pubes. A little free sanguineous fluid escaped from the peritoneal cavity. On attempting to centralize the uterus it was found impossible to insinuate the hand between it and the costal margins. The distension of the uterus was definitely limited to the body, which was of a slaty grey colour with purplish mottling, while the lower uterine segment, below the anterior peritoneal reflection which was raised to the level of the umbilicus, was elongated and showed neither grey coloration nor mottling. A longitudinal incision through the loose peritoneum over this segment exposed sufficient of it to permit a 5-inch incision into it without reflecting the bladder downwards. This incision was made in the long axis. No difficulty was experienced in extracting a well developed dead child of about 7 lb. by the presenting breech. The skin of the scrotum had desquamated, otherwise the child was in a good state of preservation. The placenta was free in the uterine cavity and was removed with three or four large dark blood clots. These clots collectively would have filled a half-pint measure. Simultaneous with the extraction of the child 1 c.cm. of pituitary extract was given subcutaneously and the uterus lifted out of the abdominal cavity. It remained flabby and toneless, and except while directly compressed there was a steady oozing from its cavity. After fifteen minutes' compression without satisfactory result gr. 1/100 ergotinine citrate was injected directly into the uterine muscle. This had the desired effect, and the uterus was preserved. The placenta was of normal shape and size, but four-fifths of the villi showed that they had been compressed. The remainder occupied an arc embracing a third of the periphery of the placenta. When the uterus was removed from the abdominal cavity, within a minute of giving pituitary extract, the intestines were seen collapsed and ivory white in colour; this persisted during the time the abdomen was open. The incisions in the lower uterine segment and in the peritoneum over it were closed separately with continuous catgut and the abdomen closed in layers.

Except for severe epigastric pain which lasted for two days convalescence was uneventful, and she went home on January 20th; the uterus had then contracted down to the size of a two to three months' pregnancy.

While concealed accidental haemorrhage is one of the rarest complications of pregnancy (1 in 15,000 or more cases), it is one of the most serious. In all but those in which the haemorrhage has been trivial the child must die *in utero*, and in those severer cases the uterine muscle is so damaged and its power of contraction and retraction so destroyed that the mother's life is endangered by the probability of post-partum haemorrhage, if not by conditions arising antecedent to the birth of the child.

To draw conclusions from one case can only be justified by the rarity of the condition, and by the hope that others will compare such conclusions with their own personal experiences. The condition has been attributed to toxæmia, trauma, emotional disturbances, and endometritis, and is commoner in multiparae. This case throws no light on the subject, but the date and hour of its onset are significant—10 p.m., December 31st.

Diagnosis offers no difficulty. The sudden onset of abdominal pain in a woman advanced in pregnancy, with marked collapse and with no "show," should suggest the condition. The tense hard swelling of the uterus, particularly in its upper segment, with inability to hear the foetal heart sounds, or uterine souffle, are sufficient to confirm the diagnosis.

The sequence of events following haemorrhage into the decidua basalis must depend on the amount of blood poured out of the ruptured vessels and on the increased intra-uterine pressure resulting. As long as the haemorrhage remains concealed between the placenta and membrane on the one hand and the uterine wall on the other the increased pressure acting through the liquor amnii tends to dilate the os to some extent, at the same time ballooning the uterus, and disseminating the fluid blood between

the bundles of uterine muscle. This sequence of events would contribute to a lowering of the intrauterine pressure if the haemorrhage ceased, but in reality it encourages further bleeding, with increased distension of the uterus and greater dissociation of muscle bundles until the intra-abdominal pressure is raised to or above that in the uterus; then the blood sinuses at the placenta site are subjected to compression which closes them and permits thrombosis to occur. It might be argued that such a state will occur earlier in a primipara or in a multipara with well developed and not overstretched abdominal muscles. Conversely, lax abdominal muscles will allow so great uterine distension that the peritoneum cracks and the dissociated muscle bundles are converted into actual ruptures permitting blood to escape into the abdominal cavity. Such cases have been described by Shannon and others. If this case can be taken as a criterion of what occurs in others, then the distension is limited to the uterine body, while the lower segment is merely stretched longitudinally and is otherwise not traumatized by the disseminating blood.

If the diagnosis could be made early, the ideal treatment would be to convert the concealed into an external haemorrhage, but as the first symptoms of concealed accidental haemorrhage arise from shock due to the rapid distension of the uterus, most cases are seen too late for this to be done without considerable risk. The firm application of an abdominal binder may assist in raising the intra-abdominal pressure and minimizing the haemorrhage.

To empty the uterus *per vias naturales* endangers the patient's life from post-partum haemorrhage, whereas if it is emptied through an abdominal hysterotomy opening the post-partum haemorrhage can be controlled by direct compression or by hysterectomy if other measures fail. If Caesarean section is performed the lower uterine segment operation appears to be more desirable than the classical method. It is the part of the uterus underlying a mid-line incision below the umbilicus; it is stretched longitudinally, and there is ample room without the necessity of reflecting the bladder downwards; it is not traumatized, at least to the same extent, as is the body; and if the uterus should become infected it is shut off from the peritoneal cavity.

The collapsed and ivory-white condition of the intestines is difficult to explain, especially as no reaction appeared during the twenty to twenty-five minutes the abdomen was open. The greatly increased intra-abdominal pressure, with irritation of the splanchnic nerves, may have had some influence in producing this state, or it may be a phenomenon of shock as described by some writers on that subject.

## A PROTEIN POISON THEORY:

ITS APPLICATION TO THE TREATMENT OF HEADACHE AND  
ESPECIALLY MIGRAINE.

BY

R. CURTIS-BROWN, M.D.,

MESTON, FRANCE.

ALL nitrogenous food, animal or vegetable, contains a potential poison. Whether untoward effects are produced or not depends entirely upon the metabolic efficiency of the individual in respect of the particular protein concerned. If the metabolic capacity of an individual is insufficient to deal with this poison, without undue reaction, manifestations are produced. These manifestations may occur in any tissue of the body, and are the symptoms of disease.

In chronic disease the reactions are so slight that they are not evident until the gradual replacement of the destroyed tissue cells by connective tissue interferes with the function of an organ. This explains the slow development of arteriosclerosis, nephritis, and other diseases of like nature. On the other hand, the manifestations may be sudden and severe, as in cyclic vomiting and migraine. Most acute manifestations show a certain periodicity, indicating a cumulative action of the poison. Other acute affections appear immediately after the ingestion of the poison, as

in the case of urticaria, angio-neurotic oedema, and the various food idiosyncrasies. Convulsions may be caused by protein ingestion, and, indeed, this is a very usual cause of convulsions in children.

My theory differs from that of anaphylaxis, which has been generally accepted to explain various food idiosyncrasies. In anaphylaxis a preliminary sensitization is required, while my theory maintains that the metabolism of the individual is inadequate. Such an inadequacy for the metabolism of nitrogenous food is most usually inherited, but further damage can be prevented by appropriate diet. The protein poison may act directly on the tissue cells of the mucous membrane or the skin, causing, for example, in the one case bronchitis or colitis, in the other such a disease as eczema. Or again, it may act indirectly, as, for example, through the endocrine or nervous system.

It is impossible in this short paper, which I wish to devote to migraine, to discuss fully the pathogenesis of protein poison manifestations, but since heredity plays such an important part in the etiology of migraine, this at any rate must be considered. The old French school represented by Trousseau, Bouchard, and Dieulafoy laid great stress upon what they called the lithaemic diathesis, and insisted on the close relationship and inheritability of gout, asthma, eczema, migraine, epilepsy, and lithiasis. They also noted the frequent occurrence of cancer in certain families which had this lithaemic diathesis. They failed to see, however, that the real basis of the heredity is a damaged protein metabolism in which protein poison manifestations can take place in any tissue or organ of the body, so producing the diseases which they attributed to lithaemic diathesis. The disease and its symptoms depend entirely upon the site of the manifestations. Each cell of the body is an individual chemical laboratory and plays a part in the general metabolism.

I consider it is quite justifiable to assume that the molecular arrangement of the cell structure, and the characteristics of the cell, upon which depends its ability to function properly, are inherited in the same manner as the general physical characteristics of the individual are inherited.

Migraine occurs in individuals who have inherited a damaged metabolism for nitrogenous foods, and I have chosen it as the subject of this paper because the remarkable results that I have obtained in its relief by the practical application of the protein poison theory have been so conclusive as to leave no doubt in my mind as to its truth and value.

Headache is one of the commonest forms of protein poison manifestation. The headaches caused by protein poison vary in severity from the mildest headache to the severest forms of typical migraine. The etiology of all functional headaches is the same. In migraine we have, however, the typical inherited insufficient protein metabolism. It is true that other causal factors, such as eye-strain, may act in producing headache, but they are secondary causes and are incapable of producing migraine if the essential cause is removed. It is quite easy to prove that protein poison is the essential cause of headache by letting a patient resume the articles of diet the omission of which caused the headache to cease. It is true, however, that some patients on a low protein diet will acquire a certain degree of tolerance for the very foods that formerly caused headache. Other patients, however, will never be able to take certain protein foods. It is most important to know that extracts from protein foods such as soups and gravies, and fruit extracts also, though they contain no protein, contain the protein poison and are very potent in causing headache; indeed, one reason why dieting has been unsuccessful in the past is because meat extracts and fruit and fruit juices have not been suspected.

I have found that skin tests are unreliable, and the quickest and best way to ascertain what foods are deleterious in each individual case is to commence with a diet free from protein, especially animal protein, and then to build up gradually a suitable diet therefrom.

The foods which I have found potent in causing headache are meat, fish, poultry, game, and extracts such as soups and gravies made from them; eggs, milk, and cheese; fruit and fruit juices; coffee, tea, chocolate, and alcohol;

and, among the vegetables, tomatoes and mushrooms. This at the first glance seems to leave nothing to eat but cereals, butter, and vegetables; and, indeed, this is the basic diet upon which to put a patient for a few weeks until his headaches are controlled. I use a diet of polished rice, butter, toast, a few green vegetables, and water.

Many patients show immediate improvement, but some are worse the first week—those who formerly had occasional headache having it continuously. This is especially true of immoderate coffee drinkers. The second week there is considerable improvement, and in the third week the majority of patients are distinctly better. In women there is usually a recurrence of headache at the first menstrual period, but after a month or two they have no more headache, not even at the menstrual period.

So soon as the headache is distinctly improved the diet should be amplified, at first with other vegetables, then by a small amount of meat once a day. Milk may be used in the cooking (many patients cannot take raw milk in any quantity) and different articles of nitrogenous food added from time to time until the tolerance for different foods is ascertained. Very few subjects of migraine can take meat soups, fruits, or eggs in any quantity. Sweetbreads, mushrooms, tomatoes, and chocolate usually must be banned entirely. With some it is necessary to omit a single article only, such as eggs. Every article of nitrogenous nature must be suspected until proved to be harmless in the particular case. The protein of cereals and vegetables is usually well borne.

It must be remembered that every food of nitrogenous nature has its specific protein. Some patients who cannot take beef can take lamb or chicken. I have had patients who were very susceptible to such proteins as unpolished rice, almonds, and peppermint. Some can take tea with impunity, but cannot take coffee; as a rule, however, most can take a fairly generous diet if certain particular proteins are omitted.

It is best that all sufferers from migraine should be on a fairly low protein diet. I believe also that the less carbohydrate and fat that is consumed the greater is the ability of the patient to metabolize protein. This may explain why some cases of migraine have been relieved by adopting a low carbohydrate or low fat diet; but I am convinced from my experience that the protein is the real causal agent of migraine.

I am well aware that the statements I make will seem somewhat dogmatic, but I am convinced of the truth of them. A single trial of this method in the most obstinate case of migraine will convince the most sceptical, and the success of his treatment will soon tempt him to apply the theory in other cases of functional disease, where it is chiefly applicable. Diseases in which organic change has already begun cannot be cured by diet, but the protein poison theory throws light upon their etiology and therefore suggests the possibility of preventing all the diseases of metabolism. It gives a new viewpoint in such serious diseases as nephritis, arterio-sclerosis, and even tumour growth.

## CANCER OF THE BREAST:

### RECURRENCE 31 YEARS AFTER OPERATION.

BY

F. J. STEWARD, M.S., F.R.C.S.,  
SURGEON TO GUY'S HOSPITAL.

I MAKE no apology for publishing a note of this case owing to its outstanding interest in its bearing on the age-long question, *When is cancer cured?*

I saw the patient a short time ago with Dr. James Bromley of Sible Hedingham. Her history was as follows:

Mrs. R., aged 81 years, was operated upon for cancer of the left breast thirty-one years ago by the late Sir Henry Bntlin. She had no further trouble until a few months before I saw her, when Dr. Bromley discovered three small hard nodules beneath the skin of the left chest in the immediate neighbourhood of the scar of the operation wound. These had slowly increased in size. During the

past two months some enlargement of the veins over the front of the left chest had appeared, and the patient complained of some degree of breathlessness and of pain in the chest.

When I examined her I found three hard nodules, as Dr. Bromley had observed. These were each about half an inch in diameter, were situated beneath the skin, and were not fixed either to the skin or to the deeper parts. These nodules were each close to the operation scar and were separated from one another by about an inch and a half. The front of the chest to the inner side of the scar was somewhat prominent, and a few dilated veins were to be seen. There was also some degree of dullness on percussion over the prominent area. The patient was rather breathless and looked ill, but not extremely so. She, however, died the same night.

There can be no reasonable doubt that the superficial nodules were carcinomatous, and that they had appeared quite recently, for Dr. Bromley was satisfied that they were not present much more than two months before my examination. There was certainly also a growth in the mediastinum, which had probably been present for some time, and which presumably caused the patient's death.

In spite of the interval of no less than thirty-one years there can be little doubt that the subcutaneous nodules and the mediastinal growth were directly connected with the original growth in the breast, and, if this is so, it would appear that carcinoma cells may lay dormant in the tissues for a period of upwards of thirty years, and for all this time give no sign, and then simultaneously, in at least four separate and distinct sites, once more become active.

What was the exciting cause of this fresh outburst of activity? Whatever it was, apparently it must have been general rather than local, otherwise the fact of four separate and independent foci becoming active at the same time cannot be explained, for, as regards the three subcutaneous nodules, as has already been mentioned, these were separated from one another by apparently healthy subcutaneous tissue, and were, moreover, all of practically the same size, and hence began to grow at the same time.

### DIAGNOSTIC VALUE OF THE SUGAR CONTENT OF THE CEREBRO-SPINAL FLUID IN ENCEPHALITIS LETHARGICA.

H. A. COOKSON, M.B., Ch.B., F.R.C.S.F.D.,  
PATHOLOGIST AND BACTERIOLOGIST, ROYAL INFIRMARY, SCANDERLAND.

So far back as 1917 it was observed by von Economo that the sugar content of the cerebro-spinal fluid was increased in many, if not in all, cases of encephalitis lethargica. During the past year I have examined a series of specimens of cerebro-spinal fluid withdrawn from patients provisionally diagnosed as suffering from encephalitis lethargica, and in all cases in which this diagnosis was finally confirmed the sugar content of the fluid was found to be increased.

The method employed for the estimation of this sugar content was that advocated by Maclean<sup>1</sup> for the determination of the sugar content of the blood: it was found to be satisfactory in over a hundred examinations of cerebro-spinal fluid in addition to those recorded in the accompanying table. By this method the figure for apparently healthy fluids was found to be within the range of 0.065 to 0.08 per cent., whilst, using Bang's microscopic method,<sup>2</sup> the average figure obtained was 0.072. Although it may be conceded that the method of Bang or Folin-Wu, or again the modification of the Benedict-Osterberg procedure used by Alpers<sup>3</sup> and others, would have given more accurate results, yet Maclean's method is nowadays so well known to many general practitioners, owing to the modern discoveries in connexion with the diagnosis and treatment of diabetes, and can be so easily performed with a reasonable degree of accuracy, that any considerable departure from the normal is readily appreciated.

It will be observed from examination of the accompanying table that in almost every case finally diagnosed as encephalitis lethargica the sugar content was definitely

increased above the normal, and that in no instance was there any diminution. Increased sugar values occur undoubtedly in certain other diseases, yet the absence of a decrease is, I think, a valuable point in diagnosing this condition from the group of other meningeal diseases, especially from tuberculous meningitis. The failure of 1 c.c.m. of cerebro-spinal fluid to reduce 0.25 c.c.m. of Fehling's solution would also probably be of value as a criterion in cases in which an estimation of the amount of sugar present was impracticable. Such a procedure, by excluding encephalitis lethargica, should be of considerable utility, whilst the indication in this way of a definite increase in the sugar content would go far towards establishing a positive diagnosis.

Table showing Sugar Content (percentages) of the Cerebro-spinal Fluid in Encephalitis Lethargica and Similar Diseases.

### Memoranda: MEDICAL, SURGICAL, OBSTETRICAL.

THROMBO-ANGIITIS OBLITERANS.  
In view of the recent article on thrombo-angiitis obliterans, by Telford and Stopford (*British Medical Journal*, December 6th, 1924, p. 1055), the following case is of interest.

A carter (British), aged 43, had been subject for twelve months to pain in the right calf and foot after walking; the pain subsided on resting, but returned on further exercise. The condition worsened in cold weather. He first noticed change in the colour of his feet seven weeks prior to admission to hospital; there was no history of injury to the foot.

Examination revealed dry gangrene of the third toe and part of the adjacent toes, the gangrene extending half-way up the artery, extending to the apex of Scarpa's triangle; elsewhere in the limb no pulsation could be detected. Cutaneous sensation of the right foot was impaired, and there was marked wasting of the muscles of both lower limbs. There was slight oedema of the foot. His general condition was good; nothing abnormal was detected in heart, lungs, or urine; the Wassermann reaction was negative.

A supracalcaneal amputation was performed. The tissues of the stump were rather anæmic; hæmorrhage was practically absent; the popliteal artery was occluded by clot and was closely adherent to the surrounding tissues. Further dissection showed thrombosis of the anterior and posterior tibial vessels.

Microscopical examination yielded findings similar to those recorded in the paper referred to.

My thanks are due to Dr. J. F. Hodgson for permission to publish this case.

H. JAFFÉ, M.R.C.S.,  
Surgeon, Royal Halifax Infirmary.

## A CASE OF LEONTIASIS OSSEA.

THE history of the case is as follows: In September, 1918, a youth, aged 18, serving in the Royal Navy, fell on the left side of his face across a 12-pounder cannon; although he had pain in his jaw he did not go off duty. About a month later he had a fight with another sailor, and was hit on the jaw. He states that his jaw "felt loose" for about a week afterwards, otherwise he was in perfect health. He was demobilized in February, 1919, and on returning home his mother noticed that the left side of his jaw was slightly swollen. In 1921 he observed slight enlargement of both nasal bones.

I saw him for the first time in January, 1924. The bony protuberances in the left side of the mandible and in both nasal bones were well marked. About March a small growth of bone started on the right side of the mandible, and the patient had considerable pain in that region. I sent him to Mr. Bernard Goodwin, F.R.C.S., in October, who diagnosed leontiasis ossæ. In November, 1924, the patient had several attacks of severe paroxysmal pain over the left side of the face.

Leontiasis ossæ was first recognized by Virchow, and is characterized by hyperostosis of the facial and cranial bones. The pathology of the disease is unknown, though probably inflammatory in nature.

The onset is, as a rule, noticed in early life, from the tenth to the thirteenth year. The chief feature is the formation of masses of new bone on the jaws; in addition to causing deformity it may interfere with sight, smell, and the movements of the jaws. The disease is of long duration, lasting twenty to thirty years, and no treatment has proved of the slightest use. A somewhat similar affection is said to occur in monkeys.

DUDLEY GILL, M.B., D.P.H., M.R.C.S.

West Bromwich.

## CREOSOTE IN INFLUENZAL PNEUMONIA, CHRONIC INFLUENZA, AND ENCEPHALITIS LETHARGICA.

In February, 1922, a note of mine on the treatment of pneumonia with creosote was published in the *BRITISH MEDICAL JOURNAL*, in which I suggested that the dose of potassium iodide usually prescribed—namely, 10 grains—was too great, and advocated the following creosote and ammonia mixture:

R. Creosol.	...	...	...	...	m℥
Pot. iod.	...	...	...	...	gr. ij
Sp. ammon. co.	}	...	...	...	āā 3ss
Sp. rectificat.		...	...	...	
Ext. glycyrrhizæ liq.	...	...	...	...	ad 3j
Aq. chloroformi	...	...	...	...	

To be given every four hours.

The potassium iodide is to be omitted in the case of patients with profuse expectoration, and not more than 2 oz. of brandy, if any, need be given in addition.

Creosote has long been used for pulmonary conditions, such as tuberculosis, and we used to give it in capsules with an expectorant mixture. Whether it is of use in early cases of phthisis I do not know, for there are cases of unresolved influenzal pneumonia, or chronic influenza as we might call them, which rapidly yield to treatment with the mixture of creosote and ammonia, and which are very liable to be mistaken for phthisis. One of my patients was, I believe, having open-air treatment for tuberculosis. He had some consolidation at the right apex and slight fever, and he rapidly recovered on being put to bed and treated with this mixture. Another was a young woman at an institution for mental defectives, who had signs suggesting a diffuse tuberculous bronchopneumonia; she had had irregular fever for over a month, and her temperature fell to normal in about three days.

I do not know whether creosote has been used for early cases of encephalitis lethargica, which is supposed to have some connexion with influenza, but it has been given intramuscularly for leprosy (*BRITISH MEDICAL JOURNAL, Epitome*, April 19th, 1924, para. 323).

London, N.W.3.

## CURE OF PRURITUS SENILIS BY THE USE OF A FLESH BRUSH.

ABOUT twenty years ago I noted in a French medical journal a letter on the value of flesh brushing in pruritus senilis. I happened to know at the time of the matron of a large nursing home who had for several years suffered severely from an intense and intractable pruritus senilis. I suggested she should try this treatment; its success was perfect: it gave immediate relief, and after a few weeks she was able to stop the treatment for intervals of many weeks. She was able to continue her work for several years afterwards.

It was long before I had another case; but it was attended by similar success. Since then it has been my sheet anchor in the treatment of this trouble. I have had a few failures, but they form only a small fraction of all the cases. The following quotation from a letter of a retired medical man is typical of what patients think of the treatment:

"After years of suffering and elaborate treatments this simple method has completely cured my wife. The simplicity of the treatment and the perfect cure can only be compared with the dipping in the river Jordan."

The treatment is as follows:

A brush resembling an ordinary bath brush but with soft bristles (a little stiffer than the bristles of a baby's hair brush) is used. The whole skin is thoroughly brushed down with it in a warm room every night, and later also in the morning if necessary. A large quantity of a whitish powder is removed from the skin. This powder consists mainly of horny epithelium. If the somewhat thinned skin of an elderly person with general pruritus is examined with a lens small refractive areas are seen glistening over the surface. Some of these may be semi-detached as a scale, others with edges separating and tilted up; the majority are flat and almost adherent. Fibres of the underclothing entangle these scales and the sense of itching is excited. The flesh brush removes the scales and cures the patient.

I do not know of any textbook in which this treatment is described. I have personally described it to many colleagues, who report to me its successes, and am publishing this note in the hope that it will prove of equal value to others as it has been to me in the treatment of these distressing if not serious cases.

A. WINKELMIED WILLIAMS, M.B., C.M., D.P.H.,  
Brighton. Dermatologist, Royal Sussex County Hospital, etc.

POISONING BY BITTERSWEET (*SOLANUM DULCAMARA*).

A boy, aged 8, was brought to us with a history of having eaten deadly nightshade berries ten minutes previously. There were no symptoms, eye or otherwise, to be noted, but the child was in a condition of nervous fright, owing to the disturbed frame of mind of his relatives. After the administration of ipecacuanha wine, and tickling the throat with a feather, a moderate amount of vomit was returned, mixed with what looked like broken-up raspberries. We obtained the plant next morning, with green and ripe red berries, and forwarded it to Kew Gardens. The Director of the Royal Botanic Gardens most kindly furnished the following report.

*Poisonous Properties.*

The plant contains the alkaloid solanin with a hot, bitter taste, dulcamarin a bitter principle, and the alkaloids solanidin and solanin.

Chesnut says with reference to this plant: The berry, though its taste is not remarkably disagreeable, is somewhat poisonous, and it has been shown that an extract of the leaves is moderately so. The plant has nevertheless caused some ill effect.

According to Schimpfky the berries have been used to poison dogs, and the juice of the fruit acts as a poison to rabbits.

Flückiger and Hanbury, in their *Pharmacographia*, make this statement with reference to dulcamara: Dulcamara is occasionally given in the form of decoction, in rheumatic or cutaneous affections; but its real action, according to Garrod, is unknown. This physician remarks that it does not dilate the pupil or produce dryness of the throat like belladonna, henbane, or stramonium. He has given a patient three pints of the decoction per diem without any marked action, and has also administered as much as half a pound of the fresh berries with no ill effect.

Johnson, in his *Medical Botany of North America*, refers to the use of the plant as follows: Bittersweet, in full doses, produces a certain amount of cerebral disturbance of a narcotic character, together with dryness of the throat, and sometimes an erythematous eruption of the skin, with a tendency to diaphoresis. It has been employed with benefit in a variety of cutaneous eruptions, in muscular rheumatism, and in chronic bronchial and pulmonary affections.

Lehmann states that it is a narcotic poison when given in large doses, even causing death in rabbits.

It will be seen from the above quotations that the plant is not a violent poison, and yet ill effects are probably produced by it under some conditions.

Ashford, Middlesex.

JOHN KENNEDY, M.B., F.R.C.S.I.

## Reports of Societies.

### THE CINCHONA ALKALOIDS IN MALARIA.

A MEETING of the Royal Society of Tropical Medicine and Hygiene was held on January 15th; the President, Sir PERCY BASSETT-SMITH, K.C.B., was in the chair. Lieut.-Colonel A. T. GAGE, C.I.E., I.M.S., librarian of the Linnean Society, read a paper entitled "A note from a cultural and commercial point of view on the use of cinchona alkaloids in the treatment of malaria."

Colonel Gage opened with an account of the commercial history of the production of cinchona bark and of cinchona alkaloids. The therapeutic properties of cinchona bark were discovered in 1638, and the reckless exploitation of the native trees led within a century to a shortness of supply of *Cinchona officinalis* in the Loja region of Ecuador, which was the original source of bark. Other sources of bark along the chain of the Andes were sought, but all valuable species tended to be rapidly exterminated by the native collectors. By the middle of the nineteenth century there was a serious shortage of bark, and the British and Dutch governments were compelled to introduce the cultivation of cinchona into their eastern dominions. Plantations were started in India early in the sixties of last century, but the trees cultivated were chiefly *C. succirubra*, a species of which the bark was poor in quinine but relatively rich in cinchonine and cinchonidine. By this date, however, quinine was in far greater demand in medical practice than were the bark preparations, and hence the serious shortage of quinine continued. The Secretary of State for India therefore ordered in 1865 that medical commissions should be appointed to determine the relative therapeutic efficiency of quinine as compared with the other cinchona alkaloids. The Madras Commission observed the results of treatment of about 3,600 cases, and concluded that ordinary quinine sulphate, chemically pure quinine sulphate, and quinidine sulphate possessed equal febrifugal power; that cinchonidine sulphate was only slightly less efficacious, and that cinchonine sulphate, though considerably inferior to the other alkaloids, was, notwithstanding, a valuable remedial agent in fever. Practically similar conclusions were reported by the other two commissions. These reports resulted in semi-official encouragement being given to the use of the alkaloids other than quinine, with the idea of substituting a cheaper product for the more expensive one. The inevitable consequence followed: the other alkaloids soared in price, and by 1875 had become more expensive than quinine. A policy of using mixed alkaloids was therefore adopted, and in 1874 cinchona febrifuge, a mixture of the total alkaloids of *C. succirubra*, began to be manufactured, and from then till 1887 was the sole product of the Indian factories. The policy of replacing *C. succirubra* on the plantations by species yielding higher quantities of quinine had been adopted, but it was not until 1887 that it was possible to manufacture quinine in India. Meanwhile the vast extension of cinchona cultivation in Java, India, and Ceylon had resulted in a production of quinine, not indeed adequate to the world's real need for it, but far in excess of the commercial demand. The price of quinine fell from £1 an ounce in 1878 to less than £1 a pound in 1890. This huge fall in the price of quinine almost killed the demand for the less attractive cinchona

febrifuge. The annual sale of the latter from the Bengal factory fell from 11,000 lb. in 1881 to a little over 1,600 lb. in 1912. Meanwhile the constitution of the cinchona febrifuge had been altered; before 1903 it represented the mixed alkaloids of *C. succirubra*, but after this date it represented a mixture of the residual alkaloids remaining after extraction of quinine from the barks of *C. ledgeriana* and its hybrid with *C. succirubra*, a certain amount of quinine being added to make it approximately similar to the original cinchona febrifuge. In 1913 an agreement was reached between cinchona planters to limit the supplies of bark, but the whole situation was changed by the war, which increased enormously the demand for quinine and forced up prices. This rise in price led to an increased demand for cinchona febrifuge.

The problem to-day was twofold. There was a relatively small population exposed to malaria and wealthy enough to pay for the best possible antimalarial remedy. On the other hand, there were large populations living in extreme poverty which were continuously exposed to malarial infections; for the relief of these the essential problem was to supply the greatest amount of efficient drug at the cheapest possible price. This latter class included the overwhelming majority of sufferers from malaria. About 90 per cent. of the world's supply of quinine came from Java, and was the product almost exclusively of *C. ledgeriana* and its hybrid with *C. succirubra*; these trees, moreover, were steadily replacing other species in India. In these two species quinine amounted to about one-half of the total alkaloids, and therefore quinine was much the most abundant cinchona alkaloid available. The other alkaloids at present might be cheaper, but their price would rise rapidly as soon as there was an increased demand. Any attempt to replace quinine by other alkaloids on a large scale would lead to serious economic consequences, for the supply of the alternative alkaloids would remain completely inadequate for many years until the cinchona plantations could be re-organized to meet the new demand. There was no reason, however, why the use of quinine should not be supplemented, and this might be effected by reverting to the cultivation of *C. succirubra*, and using its mixed alkaloids to form the original cinchona febrifuge. This species was robust, and yielded more bark than other species. If the alleviative campaign against malaria was to be continued and extended on a scale commensurate with the widespread foci of disease, two things seemed desirable: a much greater supply of therapeutic munitions at a much cheaper rate than at present available, and a great development of arrangements for placing those munitions within easy reach of the attacked.

Lieut.-Colonel CLAYTON A. LANE, I.M.S. (ret.), read a paper on certain aspects of the use of cinchona and its alkaloids in the treatment of malaria. He discussed the known facts concerning the absorption, distribution in the body, destruction, and excretion of quinine, and pointed out that they were completely ignorant of the way in which quinine caused the disappearance of malaria parasites from the blood. This action might be produced by quinine or by some metabolite of quinine. It was generally assumed that the action was exerted on the parasite in the extracorporeal stage, but no real evidence existed for this assumption. The recent work of Ricux tended to prove that quinine acts on the parasite in the intracorporeal stage. Their present ignorance of the elementary pharmacological facts as to the mode of action of quinine upon malarial parasites in the blood was a serious handicap, for such knowledge was essential in order to work out the most efficient method of administering the drug. As regards the choice of preparation of quinine for oral administration, it appeared that insoluble salts were absorbed as rapidly as soluble salts. There was a general belief that many varieties of tablets failed to disintegrate in the alimentary canal, and French writers had suggested that the sugar coating was in some way responsible for this insolubility. The value of intramuscular injections was a very vexed question. MacGillchrist's experiments on animals had proved that intramuscular injections caused a certain amount of destruction of muscle tissue, but clinical reports differed very greatly. The work of Seguin upon cases of general paralysis infected with malaria showed that it was

easy to eradicate malarial infection at an early stage with comparatively small doses of quinine. The work of Stephens in Liverpool and of Anderson in Macedonia showed that the season had a most important influence on the incidence of relapses in malaria, for these were far more frequent in the cold season. Investigators who compared the relative values of different methods of treatment should always bear in mind this important possible source of error. The work of Acton seemed to show that laevo-rotatory quinine was a specific against *P. falciparum*, whilst the dextro-rotatory alkaloids, such as quinidine, were specific for *P. vivax*. This question required very extensive and careful investigation, since any attempt to replace quinine by quinidine would necessitate extensive replanting in the cinchona plantations. The aid of the biochemist was imperative if progress was to be made in their knowledge as to the most effective manner in which the cinchona alkaloids could be used.

Mr. BERNARD HOWARD gave a short explanation of some practical difficulties associated with the preparation of quinine tablets. The acid salts of quinine absorbed moisture and formed a strongly acid solution; hence tablets of these salts must be given a moisture-proof covering. Tablets coated with pure sugar became discoloured very readily. The proposal to return to the use of mixed alkaloids was a retrograde step from the point of view of the chemist. It was almost impossible to fix a standard for the mixed alkaloids, and therefore, if the proposal was generally adopted, the danger of adulteration would be increased greatly.

Professor SWELLENGREBEL of Amsterdam mentioned that in Italy he had discovered quinine tablets with an insoluble coating. The intramuscular use of quinine had been tried very extensively in Russia, where it was used as a routine in order to economize quinine. Dutch experience had shown that malaria produced in general paralysis could always be cured by quinine, even when the patient had been allowed to have as many as twenty attacks of fever.

Sir DAVID PRAIRIE had been interested in all sides of the cinchona problem, and since he had been responsible for the production of the drugs, as well as their use, he had been keenly interested in their being used as efficiently as possible. He had always thought the amorphous alkaloids of cinchona were very important substances, although the chemist was inclined to ignore them. The various changes made at different times in the composition of cinchona febrifuge had raised steadily its content of amorphous alkaloids, and he believed that its efficiency also had increased. This fact was known to missionaries and native druggists, who preferred the cinchona febrifuge to quinine.

A visitor kindly explained the mystery regarding sugar-coated tablets. Tablets coated with pure sugar became discoloured very readily, but this was prevented by the addition of French chalk; consequently this insoluble substance was very frequently added, in varying proportions, to the covering of quinine tablets.

Sir LEONARD ROGERS recalled the amazing history of the treatment of malaria. About 1760 Lind and Clark established a treatment nearly as effective as that of to-day, for there were records of 500 cases being treated with bark with only two deaths. In 1804 Dr. James Johnson went to India for a few weeks, and on the basis of this experience wrote a book, which remained the standard textbook of tropical medicine for forty years. He taught that it was dangerous to give cinchona during fever, but that the patients should be treated with huge doses of calomel until salivation occurred. This treatment was followed universally and enthusiastically. One hospital in one month used 15,300 grains of calomel; the mortality was, of course, appalling. In 1837 a doctor was turned out of Calcutta for publishing the results of the mercurial treatment. In 1847 Dr. Haro happened to find Lind and Clark's old writings, and had the courage to revert to the use of cinchona during fever. He at once reduced the fever mortality in the Calcutta hospitals 92 per cent., and the rational use of cinchona was re-established.

Dr. W. H. MARTINDALE, Dr. HENRY, and others took part in the discussion, and Colonel GAGE and Colonel CLAYTON LANE replied to the points raised in the discussion.

## SCURVY.

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine held on January 13th, with the President, Professor A. J. CLARK, in the chair, Dr. S. S. ZILVA and Dr. G. F. STILL read papers on scurvy.

Dr. S. S. ZILVA described recent progress in the study of experimental scurvy. He pointed out that the science of nutrition and diseases resulting from disordered nutrition had received much attention of recent years and had come into the province of several sciences. He proposed to deal with scurvy solely from the chemical point of view. The war had acted as an additional stimulus to the study of deficiency diseases, and the necessity of certain food factors in a diet, although suspected for nearly fifty years, had only been worked out in recent times. The term "vitamin," introduced by Funk in the course of his work on beri-beri, had been extended in use to cover several unknown principles, and it was with reference to vitamin C that Dr. Zilva spoke. He said that scurvy was not prevalent in this country and adult scurvy was almost unknown. Treatment had been successful before the discovery of the vitamin, and cases of scurvy were always associated with deficient diets despite the beliefs of a small school in an infective factor. Experiments showed that guinea-pigs deprived of fresh food developed scurvy within about fifteen days. If an antiscorbutic substance were added to the diet scurvy could be prevented. The basic diet employed in these experiments consisted of oats, bran, and autoclaved milk, and the antiscorbutic substances to be tested were added after ten to fourteen days of this diet, the animals being killed at the end of two months in positive cases and *post-mortem* evidence of scurvy sought for. The monkey also was a suitable animal, since substances could be given in great dilution and in smaller quantities owing to the larger capacity of the stomach. Despite certain chemical methods suggested for testing antiscorbutic substances, such as the reduction of ammoniacal solutions of silver nitrate in the cold, biological methods still remained the only trustworthy tests of antiscorbutic properties. Certain facts discovered by the examination of various substances for the presence of otherwise of these properties were of great practical importance. Experiments showed that when seeds germinated they acquired antiscorbutic properties; in the malting of barley, for example, these properties could be shown to be present early in the process of "steeping" before germination was visible to the naked eye. The chemistry of the antiscorbutic factor was fraught with difficulties: chemical isolation tended to produce more impurities than vitamin. Notwithstanding this, certain important facts as to the physical and chemical properties of this food factor had been ascertained. When antiscorbutic solutions were stored under ordinary conditions they lost this property. This was shown to be due to oxidative changes. Heating antiscorbutic solutions to over 100° C. failed to destroy their potency in the absence of air. Active solutions had been inactivated by the use of hydrogen peroxide, by the ozone produced by exposure to ultra-violet light, and by less drastic oxidizing methods such as aspiration of air through a solution. While the latter procedure destroyed 80 to 85 per cent. of the activity, the aspiration of carbon dioxide produced no such effect. It was found also that solutions of antiscorbutic substances were more stable in acid solutions. Solutions rendered alkaline and left for twenty-four hours became quite inactive, while if air were excluded no such inactivation occurred. These experiments were important for they showed that the best method of storing antiscorbutic substances was in acid solutions in exhausted ampoules, and such preparations made five months ago were still potent. The isolation of vitamin C had been attempted, starting with lemon juice. This was first decitrated, the sugar was then removed by fermentation, and the vitamin-containing portion precipitated by basic lead acetate. Ninety grams of lemon juice solids gave rise to 0.3 gram of active remainder, and further work was being carried out on this. The chemical properties of this remainder showed its most conspicuous property to be that of a

reducing agent. Ammoniacal silver nitrate was reduced in the cold and potassium permanganate was decolorized, but these reducing properties were no criterion of the antiscorbutic powers of any substance. Certain physico-chemical properties related to adsorption, and diffusion had also been determined.

Dr. G. F. STILL dealt with the clinical treatment of infantile scurvy. He said that the treatment of this disease had not been affected by the laboratory work on scurvy. Dr. Cheadle recognized infantile scurvy as a deficiency disease forty-seven years ago, and he then laid down lines of treatment which were followed to-day. Dr. Still's own observations extended over thirty-two years, and 134 cases had been seen during that period. The treatment he had adopted was as effective at the beginning as at the end of that series. In experiments on animals a vitamin-deficient diet was given and antiscorbutic substances added to this, but the physician had to change the whole diet of an infant with scurvy, and hence a certain amount of fallacy might enter into the estimation of results of treatment. It was usual to take the infant off the patent food on which it was generally being fed and to put it on to cow's milk which had been heated just to the boiling point. The majority of Dr. Still's cases were treated with potatoes, and, speaking as a clinician, he suggested that the laboratory worker would find the potato a potent source of vitamin C. The potato should be baked in its skin, the central part then crumbled and mixed with hot milk to the consistency of a medium cream. Three to 4 drachms of this cream should then be given three or four times a day, added to the first portion of the feeds. The earliest sign of definite improvement was taken to be shown by a diminished tenderness of the limbs; in an infant of 9 months who was given potato cream in doses of 4 drachms four times a day, tenderness had definitely begun to disappear at the end of twenty-four hours, and it had all disappeared in eight days. After three to four doses only of this cream marked improvement was often shown, but the time for total disappearance of the disease varied with the time after onset of the disease that treatment was commenced, and blood cells might be found in the urine after all other signs had been absent for days. Potato cream used otherwise than as a temporary measure during the acute stages was apt to upset digestion; it was therefore not suitable as a prophylactic substance. Next to potato cream, orange juice in doses of 2 drachms four-hourly was valuable, but less rapid in its action. Smaller quantities of orange juice would not cure acute scurvy. Grape juice was even less potent—the juice of four grapes twice daily failed to cure one case, and raw meat juice was less active still. Orange juice in sufficiently large doses tended to produce a troublesome diarrhoea. Here the laboratory worker could be of great assistance, for by the use of a specially prepared decitrated, concentrated juice which would retain its potency over a period of months there was not the same danger of exciting diarrhoea, and huge doses could be given in safety. To an infant of 8 months Dr. Still gave the equivalent of fifteen lemons in the twenty-four hours, and at the end of thirteen and a half hours, when only two doses had been given, improvement was definitely observed. Dealing next with the prophylaxis against scurvy, Dr. Still emphasized that there was only one sure method, and that was breast-feeding. In theory a mother whose diet was deficient in vitamin C might have a milk which failed to prevent the disease, but he had never met such a case. Certain patent foods were notorious in their scorbutic properties, principally those containing malted cereals; whereas plain dried milks, on the other hand, seldom produced scurvy. The failure to prevent scurvy when such patent foods were used—was usually due to an inadequate dose of antiscorbutic substances. One teaspoonful of grape juice in the twenty-four hours was often useless. Even larger doses would fail to prevent the disease; one infant who developed scurvy at 10 months had been given three teaspoonfuls of grape juice daily from the age of 2 months. Raw meat juice in doses of one or two teaspoonfuls two or three times a day was often insufficient, and the various meat extracts were useless. Cow's milk heated just to the boiling point seldom gave rise to scurvy, but it must be carefully ascertained that the milk had not been heated

before sale. After the age of 3 months antiscorbutic substances should be added to the diet of all artificially fed infants in doses of 2 drachms of fruit juice four times a day. While orange juice was the most popular in this country, tomato juice was widely recommended in America.

The discussion which followed was brief.

## DIATHERMY FOR GONORRHOEA.

A MEETING of the Section of Electro-Therapeutics of the Royal Society of Medicine was held on the evening of January 16th. The President, Dr. STANLEY MELVILLE, made a brief reference to the death of Professor Bergonié, and those present stood in silence for a moment in deference to his memory.

Dr. E. P. CUMBERBATCH read a paper on diathermy in the treatment of gonorrhoea. His attention was first attracted to this subject in 1913, when, in the course of the experimental treatment of arthritis by diathermy, he discovered that the gonorrhoeal form was particularly amenable. Further work had revealed the fact that diathermy was an effective remedy for gonorrhoeal infections in the testis and urethra of males and in the urethra and cervix of females. The gonococcus was an organism which was peculiarly vulnerable by heat. He thought that the curative effect of diathermy did not depend entirely upon the actual "cooking" of the organisms, but also to a considerable extent upon the stimulation of the tissues to produce antibodies. Since 1918 forty-two cases of gonorrhoeal arthritis had been treated, and in every case there followed abolition of pain, reduction of swelling, and increase of movement. In the absence of actual structural changes the joint became normal. Their cases had been carefully traced and results were permanent. In epididymitis and orchitis the only sign remaining after three treatments was some thickening of the epididymis. Sixteen cases of gonorrhoeal infection of the cervix and urethra had been treated, and in four cases only could gonococci be found in the discharges after treatment. Two of these cases were probably reinfections, and gonococci disappeared from the discharges of the other two after a further course of treatment. After treatment of the prostate and vesicles of males no gonococci could be found in the prostatic fluid expressed by massage and any metastatic manifestations cleared up. Seven cases of tubo-ovarian inflammation known to be gonorrhoeal had been treated, first by diathermy to the pelvis and then later to the cervix and urethra. The pain and swelling were reduced in every case. They were still investigating the effect of diathermy on the anterior urethritis of males, and though the results were promising they were not yet able to make any definite claims for this form of treatment. Dr. Cumberbatch quoted three cases in which the effect of diathermy had been dramatic. One of the cases, a male aged 38 years, had a gonorrhoeal infection of two years' standing, with iritis and infection of the plantar fascia, which completely crippled him. Within two months of the commencement of the treatment the man was able to walk seven miles.

Dr. C. A. ROBINSON described the technique employed by Dr. Cumberbatch and himself. The diathermy machine employed was capable of having the current turned on gradually and not in large steps. This was important, as a small difference in amperage might make the difference between no burns and burns. The indifferent electrode employed was a lead belt around the pelvis, and a stand was used for the urethral and cervical electrodes. The cervix being insensitive to heat or pain extensive damage might be done before the patient gave any warning. To obviate this the sensitive urethra was treated first and the current was turned on until the sensation of heat was just beginning to change to a sensation of pain. This point was reached when the temperature of the urethra was raised to rather less than 115° F., and ten minutes' treatment of the urethra was permissible without producing any ill effects. For the subsequent treatment of the cervix one half the amperage was employed, as this had been found to produce a temperature of approximately 115° F. in the cervix, while the temperature in the rectum was about 104° F. In the

treatment of the prostate and vesicles a rectal electrode was employed and the lead belt was placed around the waist, the current increased until pain was produced, and it was then reduced slightly. Although it was impossible to determine by thermometry the temperature produced, it was estimated by analogy that the temperature in the prostate varied from 114° F. on the aspect near the electrode to 108° F. on the further aspect. He considered this treatment preferable to prostatic massage, which could only deal with organisms on the surface of the ducts. Testicular lesions were treated by means of lead plates moulded to the surface of the scrotum in place of an electrode. Salpingitis had been treated by the ordinary method of treatment of the cervix when this could be tolerated, and in other cases by the use of a vaginal electrode. No accidents had occurred in any of their cases in spite of the use of crude instruments and ignorance in the earlier work. Dr. Robinson concluded by expressing the hope that this method of treatment, for which he foresaw a great future, would not be permitted to fall into the hands of quacks. The various instruments employed were exhibited.

Dr. ALASTAIR MACGREGOR, Mr. J. J. ABRAHAM, and Dr. AGNES SAVILL had all seen the work done at St. Bartholomew's Hospital and were convinced that it was an advance in treatment.

### MULTIPLE INFECTIVE ARTHRITIS.

At a meeting of the Section of Bacteriology of the Royal Society of Medicine held on January 14th, with the President, Dr. W. EDGEcombe, in the chair, a paper was read by Dr. VINCENT COATES on clinical types of so-called multiple infective arthritis.

Dr. Coates said that the object of his paper was to attempt a simple elastic grouping of certain forms of arthritis whose etiology was, as yet, little understood—namely, (1) periarticular fibrositis, bursitis, and synovitis, (2) atrophic arthritis, (3) multiple non-specific arthritis, (4) menopausal, and (5) villous arthritis. After a brief reference to the first group, which only rarely came within the scope of his paper, the speaker passed to the group described as "atrophic arthritis"—a description he preferred to its synonyms, "true rheumatoid arthritis," "the Poncet type," etc. The salient features of the type were:

- (1) It was of obscure origin and almost confined to young females.
- (2) No obvious infective foci were to be found either in the teeth, tonsils, intestine, or urinary system.
- (3) Atrophy was conspicuous in the bones in relation to the joints, the muscles, and skin.
- (4) In well established cases the joints presented a fusiform enlargement and were symmetrically affected. There was a tendency for the smaller joints to be first affected, and there was often glandular enlargement out of all proportion to the joint lesions.
- (5) A general metabolic disturbance comprising nervous apprehension, sweating, tachycardia, pigmentation, and trophic changes.
- (6) Secondary anaemia, sometimes with a relative or absolute lymphocytosis.
- (7) Lowered resistance of mucous membranes to infection.
- (8) Various biochemical anomalies, such as absent or deficient free HCl in gastric juice, decreased sugar tolerance, and lowered basal metabolic rate. In view of this it was probable that further biochemical research on these cases might prove more fruitful than bacteriological investigation.

Multiple non-specific arthritis simulated the atrophic type, but showed the following points of difference:

- (1) The origin was not always obscure, and the sex distribution more nearly equal; also it was not confined to young adults.
- (2) Infective foci were often found, and their removal improved the prognosis.
- (3) Atrophy, though present, was not conspicuous.
- (4) The joint lesions lacked symmetry, and the glandular enlargement, if present, was in proportion to the heat and swelling of the joint.
- (5) Signs of metabolic disturbance were slight or absent.
- (6) The secondary anaemia was accompanied by a polymorphonuclear leucocytosis at some stage in the disease.

- (7) Mucous membranes not so liable to infection.
- (8) The biochemical anomalies were less constant. This group was not so definite as the last, but probably included many types of joint disease.

Menopausal arthritis (the hypoglandular arthritis of the French) occurred in women of 45 to 55, and occasionally even at a later age. Patients suffering from menopausal arthritis presented coarse synovial crepitation, usually in the knees, or villous arthritis. Trauma, increase of weight, and vascular degeneration probably played an important part, but the role of infection was less apparent. The condition of dry synovitis might develop osseous changes or villous fringes, ending in a condition of osteo-arthritis.

Villous arthritis, in the speaker's opinion, was a reaction to trauma, sepsis, or endocrine disorder, and osteo-arthritis subsequent to infection or villous arthritis should be tabulated under those disorders. Dr. Coates went on to compare the clinical types of arthritis with those recognized by Strangeways<sup>1</sup> as a result of post-mortem examinations. He concluded that (1) the two atrophic types were the same; (2) Strangeways's adhesive type was probably "multiple infective arthritis"; (3) his "dry" type was probably early "menopausal arthritis"; (4) his "capsular" type was possibly a stage of "menopausal arthritis"; and (5) his "villous" type was that described by the speaker.

A discussion followed, in which Dr. C. W. BECKLEY, Dr. H. A. ELLIS, Dr. GEORGE HOLMES, and others took part.

### OPERATIONS IN RELATION TO DIABETES.

At a meeting of the Liverpool Medical Institution on January 8th Dr. R. J. MINNITT read a paper on some toxic conditions following ether anaesthesia and their successful treatment.

Dr. Minnitt described the symptoms after ether anaesthesia in the non-diabetic case as being less than, but comparable with, those occurring in the diabetic. A definite relationship existed between the hyperglycaemia associated with ether anaesthesia and the toxic symptoms which followed. He suggested that treatment for these should be upon the lines found so successful in the case of the diabetic, and drew the following conclusions from eight out of about thirty selected cases, graphic records of which were displayed:

1. That there is a definite rise in blood sugar varying with the length of anaesthesia.
2. That in the case where the blood sugar falls at the conclusion of the anaesthesia to approximately normal, and does not rise again, the patient suffers little, if at all, from toxic symptoms, such as vomiting, pallor, or acidosis.
3. In the sugar tolerance test performed upon a case before and after anaesthesia the blood sugar curve is so altered as to show that the efficiency of the pancreas is impaired.
4. Patients who exhibit toxic symptoms after anaesthesia have a simultaneous secondary rise in blood sugar.
5. Following the administration of insulin to patients with these toxic symptoms, when the blood sugar is reduced they recover.
6. The administration of insulin may have to be prolonged until the blood sugar is reduced, for it is not until then that improvement takes place.
7. The administration of insulin at the end of ether anaesthesia can mitigate the toxic symptoms or prevent them before they arise.

[Two graphic records of the slides shown are reproduced; one illustrates the results of the sugar tolerance test, and

FIG. 1.—Post-anaesthetic hyperglycaemia and toxic symptoms reduced by insulin.

FIG. 2.—Glucose tolerance before and after operation for double hernia.

the other indicates the secondary rise in blood sugar after an anaesthetic, and the subsequent fall, with amelioration of symptoms, when insulin is administered. This research

<sup>1</sup> Proc. Roy. Soc. Med., November 12th to 14th, 1923.

work is being continued and will be published fully at a later date.]

Dr. H. S. PEMBERTON discussed the action of ether in producing hyperglycaemia of a maintained type. As Dr. Minnitt had shown, the carbohydrate tolerance was considerably diminished, so that the action of ether was probably not only glycogenolytic but was also directed against the islet tissue of the pancreas.

Mr. R. E. KELLY and Dr. J. C. MATTHEWS read a short note on the beneficial effects of insulin in diabetics requiring operations. Details of eight cases were given in which, before and after operation, the carbohydrate metabolism had been rendered more or less normal by the use of insulin. Of six patients with diabetic gangrene, four required amputation through the thigh, one patient with carcinoma of the breast, and there was one case of plastic operation on the face. No deaths occurred in the series. They considered that insulin made the operations safer, and that it certainly caused relief in the pain due to gangrene. They were also of opinion that under insulin treatment gangrene progressed much more slowly, and was consequently of a much drier type. The dosage of insulin must vary with the type of case; the difficulty of determining the dose of insulin immediately after the operation could be overcome by the examination of frequent catheter specimens or urine for sugar.

#### Radiology of the Stomach and Duodenum.

Dr. R. E. ROBERTS read a paper on the diagnostic value of x-rays in the examination of the stomach and duodenum. This was based on a survey of 319 consecutive cases in which the stomach and duodenum had been subsequently examined by the surgeon on the operating table. The direct and indirect evidence on which the radiological diagnoses were made was briefly indicated, the various points being illustrated by lantern slides. Of 47 cases giving radiologically normal findings only 2 showed any lesion at operation: in both cases the lesion was situated at the cardiac end of the stomach. In 54 cases where the surgeon found no lesion at operation, 9 had shown abnormal x-ray findings. Suggestions as to the possible explanation of these discrepancies were put forward. In 250 cases where a gastric or duodenal lesion was found at operation the pre-operative radiological findings could be arranged in tabular form as follows:

Gastric or Duodenal Lesions.

Operative Findings.	Number of Cases.	Pre-operative X-Ray Evidence.			
		Direct evidence.		Indirect evidence.	
		Site of lesion indicated precisely.	Site of lesion indicated within 2 inches only approx. indicated.	Evidence of abnormality present but not indicated.	No evidence of lesion.
Ulcer on lesser curvature of stomach, or on anterior or posterior wall	31	19	—	9	3
Organic hour-glass contraction of stomach	23	28	—	—	—
(a) Ulcer at or near pylorus with or without stenosis. (b) Simple pyloric stenosis	97	5	85	—	—
Malignant disease of body of stomach	11	10	—	—	4
Malignant disease of pyloric end of stomach	38	23	15	—	1
Syphilis of pyloric end of stomach	2	1	—	—	—
Duodenal ulcer or abnormality	43	28	7	—	6
Total	250	114	109	9	14
Percentage		45.6	43.6	3.6	5.6
					1.6

Diagnostic x-ray evidence of the lesions found at operation had thus been obtained in 232 (92.8 per cent.) of the 250 cases; 14 (5.6 per cent.) showed evidence which was not

diagnostic; whilst only 4 (1.6 per cent.) showed no x-ray evidence at all of abnormality of appearance or function of stomach or duodenum.

Mr. FRANK JEANS condemned opening the stomach, a procedure which might produce an ulcer not present before. He laid stress on a method of handling a doubtful portion of stomach or duodenum between the finger and thumb; this did no harm to the normal stomach, but produced minute ecchymosis on the peritoneum overlying an ulcer which could not be felt. The appearance was "Cayenne pepper on an oyster base"; it was a characteristic and a very helpful sign.

Dr. E. J. SERRIES had published a series some years ago in which the clinical diagnosis was compared, first, with the diagnosis made after scientific examination—chemical, bacteriological, and radiological; and secondly, with the ultimate diagnosis arrived at by operation or the subsequent development of the case. The scientific examination altered, added to, or modified the clinical diagnosis in more than half the cases. There were eight cases, just over 1 per cent., in which the diagnosis after scientific examination, including the use of x-rays, proved to be in error, but in all of these the advice given—namely, an exploratory operation—had proved to be wise. He and Mr. Maxey agreed that irregularities on the greater border, particularly near the cardiac end, sometimes gave rise to difficulty, which, however, generally disappeared on re-examination. The alteration of function was especially noticeable near the pylorus if carefully observed, particularly as Dr. Roberts had mentioned, an arrest of the peristaltic wave. He thought that direct evidence of lesion in the pyloric and duodenal regions would be obtained in a larger proportion of cases if patients were repeatedly examined in the prone position at different angles of rotation.

#### SCOPOLAMINE-MORPHINE NARCOSIS.

A clinical meeting of the Newport Medical Society was held at the Royal Gwent Hospital on December 17th, 1924, with the President, Mr. R. J. COULTER, in the chair.

Dr. REFUS C. THOMAS read a paper on scopolamine-morphine narcosis, popularly known as "twilight sleep." After giving a short history of the earlier work done, the technique recommended by Gauss was outlined, together with his own method of applying the memory test, which was characterized by him as being the essential feature in the success of the method. The effects of scopolamine-morphine on uterine contractions and the question of oligopnoea were dealt with, and the advantages of scopolamine-morphine narcosis over chloroform as an anaesthetic in labour pointed out. Dr. Thomas said that oligopnoea and post-partum haemorrhage were not encountered in any of his cases, and should not be feared provided that morphine was given only in the first dose and that the memory test was rigidly applied all through the labour, thus avoiding overdosage. The absence of shock to the mother during a prolonged labour was remarkable, and he put forward the suggestion that as the scopolamine circulated in the foetal blood also, the same anti-shock effect must also be credited in favour of the child, thus minimizing the danger to the child of shock during a prolonged labour, which he thought was undoubtedly a cause of death, either during or soon after labour, in many instances. In conclusion, he maintained that scopolamine-morphine narcosis was still not given its proper recognition. He attributed this to the many failures recorded, which he thought were due to Gauss's technique not being rigidly followed. By using the technique as outlined the mother had no idea that labour had been completed, and no harm was done to mother or child.

During the discussion which followed questions were raised as to the use of chloroform during scopolamine-morphine narcosis, the use of forceps, the question of dosage, and the indications of danger to the mother from overdosage, and the occurrence of oligopnoea. To these Dr. Thomas replied that chloroform was not needed in ordinary cases, but might be required in cases of internal version or high forceps extraction, but then only in very small amount; that forceps could be applied without chloroform

in most instances; and that the danger of oligæmæa and post-partum hæmorrhage were securely guarded against by the rigid use of the memory test, which also avoided overdose. At the same time he urged the great advantage of the method in cases of contracted pelvis, where a much longer time was required for the moulding of the head. In the ordinary way a labour such as this would be punctuated by continual requests on the part of both patient and friends to terminate the labour owing to their alarm at its long duration. Under scopolamine-morphine narcosis the patient did not suffer, and the labour could pursue a natural course without interference until the child was born.

Drs. BORD and CANDY showed a case of spleno-medullary leukaemia in a girl of 20 years. There was a history of five years' duration; anaemia was marked, and the spleen was enlarged to below the umbilicus. The case was making excellent progress under x-ray applications to the spleen and to the long bones. The red cells had shown an increase from two million to four and a half million, the leucocytes were showing a hopeful reduction, and the spleen was reduced in size. They hoped to report further progress to the society. They also showed a case of eventration of the diaphragm on the left side in a man of 45 years. X-ray examination had revealed that the stomach was displaced upwards with the lesser curvature alongside the border of the left ventricle of the heart. There were no gastric symptoms, and the condition was discovered accidentally during x-ray examination of the lungs for pulmonary symptoms.

Dr. T. MORRELL THOMAS showed a specimen of the lower end of ileum, caecum, ascending colon, and a few inches of the transverse colon, with a stricture at the hepatic flexure, which he had removed from a patient with chronic intestinal obstruction. The condition seemed malignant, but pathological examination by Dr. CATTO showed it to be tuberculous. Dr. Thomas laid stress upon the good results he had obtained in these cases by the double operation—the first to short-circuit the portion of bowel affected, and the second, about fourteen days afterwards, to remove the affected portion.

Dr. P. C. P. INGRAM showed a case of a very rare skin condition, which he described as epidermolysis bullosa.

### STREPTOTRICHOSIS OF SMALL INTESTINE.

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland held on December 5th, 1924, with the President, Dr. J. T. WIGHAM, in the chair, Sir WILLIAM WHEELER described a case of streptotrichosis of the duodenum and jejunum, and Dr. T. T. O'FARRELL demonstrated the specimens. The patient was a painter, aged 40; he had been ill for about four months, with vague abdominal pains, a temperature ranging from 99° to 101° F., loss of weight, loss of appetite, and gastric stasis. No hydrochloric acid was present in the gastric juice. There was tenderness and some rigidity over a wide area above the umbilicus. At one time during the four months his medical attendant noticed jaundice and found bile in the urine, but this symptom was very transitory. Shortly after admission to hospital the patient had a severe hæmatemesis.

The PRESIDENT thought the green colouring on the specimen must be due to bile, but in any case necrotic tissue in the lower part of the jejunum would show green colouring. The sharp line of division between the healthy and the affected parts showed that, though very serious injury had been done, the influence of the infection was strictly limited. An interesting feature of the case was the absence of any pus production.

Dr. J. W. BIGGER drew attention to the rarity of cases of streptothrix infection in Ireland; he had never seen a case like the one described. He thought that the streptothrix was usually a more spreading type of organism, which did not localize itself in granular form. He would not classify all such organisms as actinomyces, preferring to confine this term to organisms which grew in granular formation and produced clubs. It was interesting to note that this condition was not peculiar to people working with grain—a view which had been held for some time.

### Cryptogenetic Cerebral Haemorrhage.

Dr. V. M. SYKES showed specimens from a case of cryptogenetic hæmorrhage into the brain occurring in a boy aged 17.

Seven weeks before his death the patient had received a blow from a cabbage stalk on the right temple. Three days later he complained of frontal headache and vomited; after being in hospital for two weeks he went back to work, apparently well. A week later the headache and vomiting recurred, and he became stupid and drowsy. The day before his death he had several fits and very severe headache, the right arm and leg became spastic, a semi-comatose condition developed, and the temperature rose to 101°. In the evening the left arm was completely paralysed, the right arm partly paralysed, and both legs spastic, especially the right. No injury to the skin or subcutaneous tissues of the scalp was found; there was no fracture of the skull, the dura was normal, and there was no laceration of the surface of the brain. A large hæmorrhage external to the right internal capsule in the substance of the brain was accompanied by a large area of softening. This area of softening had opened into the anterior horn of the lateral ventricle, and both lateral ventricles contained recent blood. A recent hæmorrhage also extended outwards from the area of softening to the Sylvian fissure, and there was recent hæmorrhage on the under surface of the frontal lobes and base of the brain. The heart, blood vessels, spleen, and lungs appeared healthy; there was no sign of syphilis, and no hæmorrhages elsewhere in the body. Sections of the brain showed oedema of the brain substance and hæmorrhages round the small vessels. There was no sign of vascular disease or of tumour. The heart muscle showed some granular degeneration of the fibres, and the liver and kidneys slight parenchymatous changes.

The PRESIDENT suggested that there had been originally a congenital malformation of vessels, which might, with very slightly increased pressure, rupture. The appearance of the sections was striking, as there was blood round all the capillaries—apparently the result of the first hæmorrhage, as the cells were mostly decolorized.

Sir W. WHEELER drew attention to the increasingly large number of hæmorrhages into the brain which occurred in young children, both intradural and extradural. Recently he had seen in hospital a child, aged 9 years, who was stated to have fallen but did not seem to have been hurt, and later, passing into a state apparently due to cerebral compression, became comatose and died. At the necropsy extradural hæmorrhage from a ruptured middle meningeal artery was found.

Dr. O'FAHRELL referred to a case of acute lymphatic leukaemia, in which the cause of death had been cerebral hæmorrhage. The condition in this case, however, was mainly inflammatory. In these cases it was necessary to exclude the possibility of a tumour, leukaemia, or a syphilitic endarteritis.

Dr. SYKES, in reply, said there had been no history of previous brain trouble in his case. He thought it would be impossible to exclude definitely a brain tumour, but in the majority of these cases no trace of tumour was found. He had only seen the patient the night before death and so had no opportunity to get the blood examined, but the spleen was perfectly normal and there was no glandular enlargement. There was some granular degeneration in the heart muscle.

### Double Congenital Cystic Kidney.

Dr. D. DOUGLAS showed a specimen of double congenital cystic kidney in a stillborn child. The mother stated that this was her second child, and that the first had been similar. In this case the thymus was larger, the heart normal, and the lungs small and contracted; there was a certain amount of hydrocephalus, and the kidneys were enormous.

Dr. SYKES thought that in the majority of cases of cystic kidney cysts were found in the liver also; this would dispose of any embryological explanation of the condition.

Dr. C. M. WEST had had a somewhat similar case sent to him from the Rotunda Hospital which he was now investigating. In his case, however, only one kidney—the right—was cystic, and the ureter was as large as the aorta. The bladder extended up to the umbilicus, to which its apex was adherent. It seemed to him to be a case of cystic kidney combined with hydronephrosis, and he thought the condition was due to obstruction of the urethra.

Dr. O'FARRELL referred to a case in which both kidneys were found to be large and almost completely cystic throughout, yet the patient, a man, had lived to adult life: in this case there was also a cystic condition of the liver. He thought Dr. West's case was probably one of obstruction in the urethra. He referred to the difficulty of diagnosis in these cases; uraemia was usually the first symptom discovered.

Sir W. WHEELER said that patients suffering from congenital cystic kidneys often lived to adult life. He referred to the want of fusion between the mesothelium and Wolfian duct portions of the kidney, and the classification of tumours adopted in the Mayo clinic.

*Cylindroma of the Cheek.*  
Dr. O'FARRELL showed a specimen of cylindroma of the cheek.

The patient, aged 58, was admitted to St. Vincent's Hospital with "a lump on the jaw" which he had first noticed when it was the size of a small pea, about ten years ago; it had been growing slowly since, and on one occasion had been lanced. On admission a hard nodular mass, about the size of a hen's egg, was found on the right side of the face. The tumour involved a triangular area extending from the angle of the mouth to the root of the right ala nasi, and extended outwards and backwards to within 2.5 cm. of the lobe of the right ear. The new growth appeared to be divided into three lobules, of which the middle was the largest: it was not fixed to the bone or skin but extended to the mucous membrane of the mouth, which at this point was red and swollen but not tender. Many of the teeth were carious, particularly upon the same side as the tumour. The growth was removed by operation and the patient made an uninterupted recovery. To the naked eye the specimen was an encapsulated tumour, measuring  $5 \times 3 \times 4$  cm., it was more or less nodular on the surface, and at one point a cyst, about the size of a hazel-nut, was found. On section the tumour was irregularly lobulated, but for the most part the cells were arranged in columns, the centre of each column being in a condition of hyaline degeneration. Many small cysts, formed by dilated lymphatics, were found throughout the section. The specimen could be described as a cylindroma or a lymphoangio-endothelioma with hyaline degeneration.

The PRESIDENT thought these tumours were usually connected in some way with the parotid gland, and that they were really locally malignant, and likely to recur. Dr. SYKES asked if Dr. O'Farrell regarded this tumour as simple or malignant; under the microscope it seemed to be cellular in structure. Sir W. WHEELER said that if this tumour was malignant the prognosis was bad: he regarded any form of cancer of the cheek as extremely fatal. Dr. O'FARRELL said that the tumour had no connexion with the parotid; he did not regard ordinary mixed tumours of the parotid as malignant.

### PELVIC ADENOMYOMA.

A MEETING of the North of England Obstetrical and Gynaecological Society was held at Manchester on December 19th, 1924, Professor A. DONALD, the President, occupying the chair. Specimens and cases were shown by the PRESIDENT and by Drs. BLAIR BELL, FOTHERGILL, IVES, FLETCHER SLAW, and DOUGAL; and Dr. KENNETH BAILEY read a paper on the pathology of ectopic müllerianoma, more commonly known as pelvic adenomyoma or chronic adenomyositis.

Dr. Bailey said that there could be no doubt that the pelvic tumours met with in this disease were produced by the invasion of the various pelvic organs and peritoneal surface by endometrial tissue or Fallopian epithelium; and since there was a marked difference in the lesions resulting from the invasion of these two tissues, he proposed to classify the tumours under the headings of endometrial and Fallopian. It was noticeable that the effect of the invasion varied considerably with the organ affected—the uterus showed great activity and exhibited the characteristic stages of the lesion in their entirety. The course of the endometrial type of lesion could be divided into six stages. In the first stage a small deposit of endo-

metrial tissue, consisting of uterine epithelium and stroma, adhered to the surface of the ovary. In stage two the endometrium commenced to invade the ovarian tissue, producing a small haemorrhagic excavation or bleb, and, immediately beneath the surface, a pseudo-cyst containing active endometrium and extravasated blood. In the third stage a downgrowth into the ovarian stroma occurred, either in the form of a linear track containing a clump of active endometrium at its termination, or, when the invasion extended laterally as well, in the form of a wedge. In the process of invasion the glandular elements were preceded by masses of stroma. In the fourth stage degeneration commenced in the invading elements. The change was visible to the naked eye as a seam of chocolate-coloured fluid blood stretching into the ovarian tissue, and containing degenerated epithelial cells, phagocytes, and cellular debris. The fluid seemed to represent the retained product of the menstrual activity of the endometrium. Stage five was marked by the commencement of cavity formation in the ovarian tissue; and in stage six the ovary was transformed into a distended sac of the size of a Tangerine orange, containing chocolate-coloured fluid blood. In this stage the ovary was always found to be densely adherent to surrounding structures, the adhesions probably commencing around the orifice formed by the initial deposit. The tissue found in these blood cavities was considered to be endometrial because it was morphologically identical, concurrently with menstruation—occurring in the uterine cavity, and it could be shown on fairly strong evidence to be derived from the uterine cavity. Endometrial invasion of the uterine body from without exhibited essentially similar changes, limited, however, to the first three stages, the last stage being characterized by regressive changes in the misplaced endometrium. The glands became widely dilated and lined with cubical epithelium, were either empty or contained altered blood, and were surrounded with a thin zone of stroma exhibiting no invasive activity. The course of the Fallopian type of lesion was divisible into four stages, the first consisting in the deposition of a small mass of Fallopian epithelium on the surface of the ovary, the cells being columnar in form and ciliated. In the next stage invasion of the ovarian stroma commenced, a minute indentation lined with the invading cells being produced. No stromal bed was present such as occurred in the endometrial type. In stage three penetration of the ovarian stroma continued until one or more gland-like spaces were formed at short distances below the ovarian surface, lined with columnar epithelium and resting directly on the ovarian stroma. Rarefaction of the surrounding stroma was slight and resulted from extravasation of blood. In the fourth stage degeneration of the misplaced Fallopian elements commenced. Very little further penetration took place; the ovary was never deeply invaded and there was no excavation. Apparently the Fallopian epithelium was unable to invade the musculature of the uterine body, but evidences of such invasion were found beneath deposits on the ovarian ligament and wall of the Fallopian tube. In order to obtain evidence that the deposits were derived from the uterine and Fallopian mucous membranes Dr. Bailey examined the pelvic organs affected by the tumour and removed during menstruation. Free epithelial elements were found to be present in the uterine cavity and the lumen of the interstitial, isthmic, ampullary, and fimbrial portions of the Fallopian tube. Dr. Bailey suggested the name "müllerianoma" as being suitable for the disease.

In connexion with the sixth congress of the Far Eastern Association of Tropical Medicine, to be held at Tokyo from October 18th to November 7th, special reports on the prevention of beri-beri will be contributed by delegates from various governments. During the first week of September the general session of the International Conference of the fourth will also be held at Tokyo.

The twentieth Dutch Congress of National Science and Medicine will be held at Groningen from April 14th to 16th. The medical section is under the presidency of Professor C. F. A. Koch.

## Reviews.

### MONRO'S "MEDICINE."

AMONG the standard textbooks of medicine in the English language Professor T. K. Monro's *Manual of Medicine*, now in its fifth edition<sup>1</sup> and in its twenty-second year, has a deservedly established position as a clear and thoroughly sound book for students. It is somewhat on the lines of the late Dr. J. S. Bristowe's once well known treatise, and differs from the textbooks of Hilton Faggo and Osler in showing rather less of the personal touch so characteristic of these works, though there are footnotes to some of the eponymous diseases, such as Huntington's chorea, Parkinson's disease, and Graves's disease, giving dates or other brief information; as might be expected from such a famous bibliophile of Sir Thomas Browne, there is a reference to the Knight of Norwich in a footnote about malaria. Epidemic, or, as it is called, lethargic, encephalitis now appears among the specific infections, and five clinical types, including the myoclonic form and epidemic hiccup, are described; but in the brief notice of electric (Dubini's) chorea later in the volume no hint of its probable identity with the myoclonic form is given. Brief notes on the subjects of tularaemia and seven-day (saku) fever also appear for the first time.

The specific infections, among which rheumatic fever is included, occupy about a fifth of the volume, and are followed by the section on constitutional diseases, such as gout, diabetes, achondroplasia, chronic rheumatism and osteoarthritis, obesity, and deficiency diseases. After this the various systems, beginning with the cardio-vascular, are dealt with; in the discussion of the pathology of angina pectoris, after mentioning the explanations of coronary obstruction, Sir Clifford Allbutt's view of suprasigmoid disease of the aorta, and Professor J. A. MacWilliam's belief in ventricular fibrillation, the author adopts as a working hypothesis the late Sir William Broadbent's conception that angina is a defensive mechanism against excessive strain, or, in Sir James Mackenzie's phrase, "a reflex protective phenomenon." There are a number of polygraph and electrocardiographic illustrations provided by Professor Monro's chief assistant, Dr. George A. Allan.

Hodgkin's disease is placed among the diseases of the blood, whereas it might with perhaps more justification have been associated with the proved infective granulomata; in a footnote it is stated that cases had been described before Hodgkin's paper in 1832, but as in the later account of Thomsen's disease, in which a similar remark is made, the reader is tantalized by the absence of further information. The work of the Glasgow school is rightly mentioned in various places—for example, in the section on the ductless glands, in the references to digestion of the oesophagus during life and when discussing Gairdner's "gastric vescent." Dr. J. W. McNee's recent classification of jaundice is adopted by his former teacher, and reference is made to Hijmans van den Bergh's test for bilirubin in the blood serum as a means of differentiating obstructive hepatic from other forms of jaundice. Infectious jaundice is described among the specific infections, and rightly so as far as spirochaetosis icterohaemorrhagica is concerned, which indeed is the only form mentioned under the heading of infectious jaundice; but it may be suggested that it would be better to remove the heading and let spirochaetosis icterohaemorrhagica take its place, for there are other forms of jaundice due to infection. The new tests for renal efficiency are described and the diseases of the skin are epitomized.

In conclusion, it may without further analysis be confidently said that this is a well written, up-to-date textbook, such as would be expected from an experienced and conscientious teacher who knows what students need and how to supply them with the necessary information.

### ACUTE INFECTIOUS DISEASES.

THE reader will expect a work on *Acute Infectious Diseases*<sup>2</sup> by a skilled observer, based on a quarter of a century's experience in the hospitals of the Metropolitan Asylums Board, to be authoritative; and the reader will not be disappointed. Dr. J. D. Rolleston deals only with those diseases which are mainly or exclusively treated in isolation hospitals, so that what is said as to symptoms, treatment, prognosis, and so forth is the outcome of personal observation and study. Cerebro-spinal fever is the only disease discussed of the group of infections especially associated with the central nervous system; but whooping-cough, Vincent's angina, mumps, rubella, the so-called "fourth disease," and erythema infectiosum are all included. In the typhoid group the three paratyphoid fevers A, B, and C are briefly discussed in relation to their bacteriology, clinical features, and course. In dealing with typhoid fever itself, Dr. Rolleston refers to the experience of Jenner and Murchison, that diarrhoea characterized the great majority of cases, whereas in the present day, though the stools are loose with the pen-soup character, yet constipation is the rule except in severe cases, an enema being required every other day. The author considers that in most cases relapse in typhoid is probably not due to reinfection, but to a mobilization of the typhoid bacilli, which have remained inactive in the gall bladder or elsewhere, but return to the blood stream and then reinvade the intestine. That being so, then on the whole "mild attacks are more likely to be followed by relapses than are severe attacks, which seem to confer a greater degree of immunity upon the patient." Concerning the occurrence of the disease in the inoculated, he has found that the attack is generally much milder, shorter, and uncomplicated. Regarding small-pox, Dr. Rolleston makes one statement on a matter of great practical importance, which he would do well to reconsider. He writes, "The small-pox patient is infectious in all stages of the disease, even in the incubation period, before any symptoms have appeared." But the whole policy of surveillance of contacts is based on the view that in the purely incubation stage, before the primary fever has begun, the case is not infectious, and a man may be allowed to follow his employment until the period of invasion approaches, the date of exposure to infection being known. In reading Dr. Rolleston's excellent handbook this is the only point where we have found occasion for criticism, and even here the question arises whether the author has made his meaning clear, and, if so, on what experience his opinion rests. The work is thoroughly practical and up to date, and will be of the greatest use to practitioners and students.

### A TEXTBOOK OF PHYSIOLOGY.

THE reviewer's first thought on handling Professor Roaf's *Textbook of Physiology*<sup>3</sup> is, Can there really be a call for another textbook on this subject? The medical student, that object of the earnest solicitude of so many writers on biological subjects, seems so well provided already with guides to the intricacies of the science of life that one more book, we should imagine, would go unread. But Professor Roaf has dealt with his subject in a rather original manner. He views the living body under four aspects—the mechanical, chemical, regulative, and reproductive. From the point of view of the beginner this is a welcome departure from methods which have become stereotyped. It leads here and there to some curious results, as, for instance, when we find in the middle of the chapter on foods a description of Nicol's prism.

We heartily agree that it is wise to deal as early as possible with the mechanics of the body—the maintenance of the erect posture, the place of the centre of gravity, and the dynamics of walking and of equilibration generally. It is annoying to fail to find anything in a textbook of physiology that would throw light on the many problems that have to be solved by the student of orthopaedics. Hageraft's

<sup>1</sup> *Manual of Medicine*. By Thomas Kirkpatrick Monro, M.A., M.D. Fifth edition. University Series. London: Baillière, Tindall and Cox. 1925. (Demy 8vo, pp. xviii + 1033; 55 figures. 25s. net.)

<sup>2</sup> *Acute Infectious Diseases: A Handbook*. By J. D. Rolleston, M.A., M.D. Oxon. (Medical Books), Ltd. 1925. (Demy 8vo.

<sup>3</sup> *A Textbook of Physiology*. By H. E. J. M.R.C.S., L.R.C.P. London: Edward Arnold. 1925. (Demy 8vo, pp. viii + 605; 325 figures. 25s. net.)

excellent article in Schafer's large work is freely drawn upon, with all acknowledgements. Since Part I deals with bio-mechanics, we find included here the haemodynamics of the circulation and the muscular mechanism of breathing. This is a new plan, but it is perfectly logical and has much in its favour. Here too we find, justified by the same principle, a discussion of the heat and electrical phenomena of muscle. It is clear that these things can be studied without any reference to their underlying chemical bases, and this is an example of how to do it.

The excellence of the illustrations must be remarked on before any other feature of the book is noticed. There are 325 figures, the great majority of which cannot be praised too highly; only one of them—the photomicrograph of a section of the uterus—is indistinct. Professor Roaf never commits the mistake of describing a piece of apparatus which is not figured; but we fail to see the object of representing in the appendix just seven pieces of apparatus for use in the students' laboratory. The diagram of the events of the cardiac cycle on page 68 would, to some students, be worth the price of the book; it is certainly an instructional *multum in parvo*.

Professor Roaf has evidently experienced the difficulty common to all writers on physiology of deciding how much histology to include. While sympathizing with the trouble this subject always involves, we are puzzled to understand why the list of methods of staining tissues should be inserted just where it is—towards the end rather than at the beginning of this part. We are disposed to think also that the consideration of the lymph has been postponed too late a place in the book; the student cannot too early have a very concrete idea of the place and functions of the lymph in metabolism. We do not find a sufficiently full account of the functions of the cranial nerves. The physiology of these nerves is of the highest consequence to the student, far higher than the illusion of Zöllner's lines or of haploscopic vision. The subject of voice and speech is treated very briefly, and the vexed question of a speech centre is not wrestled with; and we have sought in vain for any reference to aphasia, anarthria, agraphia, and alexia. The omission of any reference to the muscular sense (kinaesthesia) is also unfortunate, and we would have welcomed much more on sleep and its relations to types of insomnia.

### THE LITERATURE OF PHARMACOLOGY.

The second half of the second volume of HEFFTER's handbook of experimental pharmacology<sup>4</sup> contains 1,400 pages; the first half of the second volume contained 600 pages and the first volume 1,300 pages, and the work is to be completed in three volumes. These figures give an idea of the scale of this work, which aims at being an encyclopaedia of pharmacology, and seeks to give an account of practically all the work that has been done in this subject. The book is international in character, for it was planned before the war, and scientists from most European countries have contributed. The following are the most important articles in the second half of the second volume, which is the portion under review.

Professor Cushny of Edinburgh contributes articles on atropine and ergot. Professors Dixon and Ransom have written five sections dealing with a large number of drugs, the most important of which are nicotine, pilocarpine, and physostigmine. Professor Starkenstein of Prague has written a monograph of 300 pages on the opium alkaloids, and gives a very full account of their chemistry and pharmacology.

The article upon adrenaline and allied bases, by Professor Paul Trendelenburg (150 pages), contains a very complete account of all the work that has been done upon the pharmacological action of these substances. Very little is said about the endocrine action of the suprarenal bodies, which alone is an enormous subject; but, even with this side of the problem in large measure omitted, the papers to which references are given number nearly 2,000.

Professor W. Straub of Munich has written 100 pages on the pharmacological action of the digitalis glucosides and

their allies. He has paid special attention to the action of these substances on the heart of the frog, and his analysis of the subject is illustrated chiefly from experiments of his own. The subject is treated strictly from the pharmacological standpoint, and consequently little is said about the action of digitalis on diseased tissues.

Other noteworthy articles are two by Professor R. Magnus of Utrecht upon purgatives and one by Professor E. S. Faust upon animal poisons. The volume contains also shorter articles dealing with cannabis indica, hydrastis, phlorhizin, saponins, bitters, tannins, and flix mas.

This summary shows that many of the most important drugs used in therapeutics are here dealt with. A general survey of the book creates chiefly a feeling of surprise at the enormous amount of pharmacological work that has been done during the last fifty years. The total number of references given must number nearly 15,000, and this in spite of the fact that most of the writers have confined themselves to the chemical and pharmacological aspect of the problems dealt with, and have said little about the therapeutic uses of the drugs described.

We cannot help feeling, however, that there is an awkward gap between the results of the colossal amount of work summarized in this volume and clinical medicine, for it is a long step from the action of a drug upon a healthy animal to its action upon the diseased human being. Unfortunately the reliable work that has been done to bridge this gap is scanty compared to the vast bulk of purely pharmacological research. The value of the work under review would have been greatly increased if more space had been devoted to showing the relation between the ascertained pharmacological actions of the drugs and their clinical uses. An accurate knowledge of the elementary pharmacological actions of drugs is, of course, an essential foundation for the understanding of the more complex problems of therapeutics; but still there seems a lack of proportion between the large amount of research in pure pharmacology and the scanty evidence available concerning the exact mode of action of drugs in disease. Controlled observations are, of course, extremely difficult to make in clinical practice, but remarkably few observations seem to have been made to determine the differences in the reaction to drugs of healthy and diseased animals.

The limitations of the book under review are perhaps unavoidable, and within its limits it will be found extremely useful by those who wish to obtain a full summary of the evidence concerning the purely pharmacological action of any particular drug.

### DISEASES OF CHILDREN.

The volume by Professor Nobécourt of Paris, on affections of the respiratory apparatus,<sup>5</sup> is described as the first instalment of a series of clinical studies, intended to be complementary to his *Précis de Médecine des Enfants*, which follows the usual lines of a systematic treatise of medicine. But in the present volume he does not describe types, but the individual sick children, relating the history and detailing the symptoms and signs of disease observed, the diagnosis reached, the treatment applied, and the progress and result of the disease; finally, the case is discussed in relation to the type of disease and to certain general principles of pathology and treatment that are illustrated by this individual and perhaps atypical example. Laryngitis in mesles; subacute and chronic bronchopneumonia and bronchiectasis in children; parapneumonia and metapneumonia pleuritis; the encephalo-meningeal reaction in pneumonia; the evolution of pulmonary phthisis in later childhood; whooping-cough and tuberculosis—these are some of the twenty chapters headings. This is a difficult kind of medical writing, in which success is achieved only by an experienced physician and teacher. But Professor Nobécourt has both these qualifications; and in this first volume he has done his work well, and will certainly make us look forward to a continuation of these clinical studies. They are the ripe fruit of long experience. *Ars longa*; or, in his own wise and

<sup>4</sup> *Handbuch der experimentellen Pharmakologie*. Edited by Professor A. Heffter. Second volume, second half. Berlin: Julius Springer. 1924. (Sup. roy. 8vo, pp. 599–1974; 184 figures. Dollars 20.75.)

<sup>5</sup> *Clinique Médicale des Enfants: Affections de l'Appareil Respiratoire*. Par P. Nobécourt, Professeur de Clinique Médicale des Enfants à la Faculté de Médecine de Paris. Paris: Masson et Cie. 1924. (Cled 8vo, pp. xi + 348; 54 figures. Fr. 22 net.)

modest words, "Ces études, il ne les achèvera jamais; il devra les poursuivre aussi longtemps qu'il pratiquera la médecine."

A short and clear monograph on bronchopneumonia in the infant<sup>6</sup> has been published by Dr. JUAN MEYER of Paris, based on personal investigations, both clinical and scientific. While the whole scope of the subject is reviewed, special attention has been devoted to certain aspects, especially to the factors of anoxaemia and dehydration. The dehydration indicates the varying degree of poisoning of the tissues, and in certain cases is the predominant factor. The author describes his method of measuring the daily loss of water: this is done by two weighings of the infant at the interval of one hour, and from this is derived by calculation the amount of water lost in twenty-four hours from the skin and in the expired air. Two severe types of bronchopneumonia are thus differentiated—a diminished loss of water, leading to a grave condition of anoxaemia; and an excessive dehydration with rapid loss of weight and a grave toxic condition. In a careful though brief review of methods of treatment, both old and new, the capital importance of daily warm baths and of abundant pure air is insisted on. Among more modern methods the value of serum therapy and of oxygen administration is discussed. Large doses of antipneumococcal serum are advised, and the author's own method of administering oxygen is described. While no very definite results are claimed, Dr. Meyer believes that some desperate cases can be saved by these means. He is to be congratulated on the clear account of his investigation, on his scientific methods, and on the cautious reserve of his conclusions.

Professor E. SUÑER of Madrid has secured the translation into French by Dr. MATHÉ of some lectures on digestion and nutrition in infancy. They profess to deal with the physio-pathology of the digestive apparatus in infancy,<sup>7</sup> but are more concerned with physiology than with pathology, and the slender volume gives only an incomplete and general sketch of a large and complicated subject. The author, however, is acquainted with his subject, and also with the oceanic literature which has been poured out over it; and in his seven chapters he succeeds in giving a clear and reliable account of some aspects of digestion and nutrition in infants without encumbering his pages with many facts, theories, or names of individuals. To change the metaphor, it may be said that in this bareness and generality of statement he relieves the subjects of the mountainous accretions that have been piled on it by the patient labours of the chemists and medical theorists. A brief account of the digestive ferments of the alimentary tract, the bacterial flora in both normal and abnormal conditions, the constitution of the albuminoid molecule, the significance of basal metabolism and of calorimetric methods, some points about mammary secretion and the management of breast-feeding, and a short sketch of the various theories of the dyspepsias of infancy, are the chief contents of the book. It is a casual but thoughtful commentary upon some aspects of that formidable subject known as "infant feeding."

The book on infant therapeutics in daily practice,<sup>8</sup> by Dr. K. BLÜHORN of Göttingen, deals in less than two hundred pages with the commoner diseases of infancy, and with the dieting of healthy infants. Indeed, the latter subject and the disorders of digestion occupy about one hundred pages, so that the space left for other diseases is very limited. Condensation is, in fact, carried to a dangerous degree; the book is neither a sufficient introduction to nor a safe and adequate presentation of the important subject with which it deals.

## MAGIC AND MEDICINE.

THE first two volumes of Canon JOHN ROSCOE's report of the Mackie Ethnological Expedition to Central Africa were reviewed by Sir Arthur Keith in our issue of August 18th, 1923. The third and last volume has now been published.<sup>9</sup> It deals with the Bagesu and other tribes living on the slopes of Mount Elgon, a hilly country to the north-east of Lake Victoria, and also with sundry peoples near the Ruwenzori range and Lake Edward. All these tribes live within the area of the Uganda Protectorate; and as the country is brought into a more settled state by the British Government, the former mode of life of the natives ceases and many of their customs disappear. The origin of these pastoral people of the lake region is still a mystery, though there can be little doubt that they were immigrants from the north-east, and were associated in the remote past with the dwellers in Egypt. A record of their habits of life while still unaltered by the advance of civilization is important for the solution of the mystery, and Canon Roscoe's notes will be of value to future workers. A general description is given of the various tribes, with an account of their religion, their occupations, the customs connected with birth, initiation, and marriage, the procedures in sickness, death, and inheritance, and their language. The Bagesu tribe on Mount Elgon is one of the most primitive of the negro tribes of Africa; it consists of numerous small clans, all at enmity with one another. As, however, they enforce clan exogamy, an armistice takes place once a year after the harvest; all weapons are stowed away, and the people wander from village to village singing, dancing, and drinking beer, while the young men and women who are ready for marriage choose their mates. The religious beliefs of most of the tribes described are vague; but many believe in a creator, though they do not often trouble him with requests. The belief in spirits is widespread, and some races have gods of plague or small-pox. Magic is largely practised, and ghosts are propitiated. Sickness is often attributed to the action of ghosts, and the medicine man is called in to find out whether the illness is due to malevolent or to dissatisfied friendly ghosts. The decision is arrived at by inspecting the organs or entrails of birds and animals which have been sacrificed to the ghost. At the same time more rational treatment is often carried out, as amongst the Busoga; by them a patient with small-pox is isolated and nursed by someone who has had the disease. The nurse pricks the pustules and sponges away the pus. Bleeding and treatment by herbs are used in many forms of illness; in abdominal troubles an enema of hot water may be given and the patient carried outside the hut to defaecate. In some tribes very little attention is given to the sick person; if he cannot eat his food he goes without, his wife going out to work in the field as usual. The ceremony of initiation seems to involve in some tribes very extensive circumcision, both in the male and female. Some of the tribes practise cannibalism; and the Bagesu appear to eat their dead in order that the ghost may not be detained in the vicinity of the place of death and cause illness to the children of the family.

Canon Roscoe's work is a valuable contribution to the ethnology of Central African people; he is to be thanked especially for having observed and placed on record manners and customs which are fast disappearing.

## NOTES ON BOOKS.

THE *University of Pennsylvania Bulletin*<sup>10</sup> has reprinted *Contributions from the William Pepper Laboratory of Clinical Medicine*. They are records of fine and painstaking work in the clinical laboratory, and include a notable paper in which the functional and anatomical findings in a series of cases of renal disease are compared by Dr. Alfred Stengel and others. The conclusions briefly are: (1) that cases clinically and histologically renal arterio-sclerosis present to the naked eye considerable variations; (2) that cases with high blood

<sup>9</sup> *The Bagesu and other Tribes of the Uganda Protectorate*. The third part of the report of the Mackie Ethnological Expedition to Central Africa. By John Roscoe, M.A. Cambridge: The University Press. 1924. (Demy 8vo, pp. xiii + 205; 32 plates. 20s. net.)

<sup>10</sup> Philadelphia: Press of the University of Pennsylvania. 1923. (Imp. 8vo; illustrated.)

pressure show some fall in pressure before death and that the diastolic pressure falls proportionally to the systolic pressure; (3) that cases of acute nephritis show rather pronounced impairment of all the renal functional tests. Another clear and valuable contribution is on the laboratory as an aid in the treatment of diabetes. This is from the pen of Dr. Leon Jonas, who deals particularly with tests designed to determine the severity of a case and also to act as guides in treatment. He emphasizes the need of using methods which have passed out of the experimental state, and the great value of laboratory work. In addition to these there are papers dealing with the chemistry of acidosis and the treatment of auricular fibrillation by quinidine sulphate. The publication is well printed, the illustrations are good, and both the medical consultant and the laboratory worker will find it perusal valuable.

The third edition of *Lang's German-English Dictionary of Terms Used in Medicine and the Allied Sciences* has been edited and revised by Dr. M. K. MEYERS. Over 4,000 new terms have been incorporated, and this edition contains approximately 53,000 definitions. The volume is well bound and clearly printed, and will be very useful to those engaged in the task of translating German medical publications.

The second edition of the textbook of infectious diseases,<sup>12</sup> by the late Professor G. JOCHMANN of Berlin, who died of typhus contracted from Russian prisoners of war in January, 1915, has been published on the occasion of the centenary of the foundation of St. George's Hospital, Hamburg. Professor HEGLER of that city, whose knowledge of infectious diseases was gained not only in Germany but also in the Balkans and Mesopotamia during the world war, in addition to studying the work to general revision has added new chapters on epidemic encephalitis, Weil's disease, trench fever, and trichinosis. The chapters on malaria and blackwater fever have been revised by Dr. NOCHT, and those on varicella, variola, and vaccination by Dr. PASCHEN, who has added a new chapter on herpes. The work, of which the first edition was published in 1914 shortly after the outbreak of the war, has one remarkable feature—namely, that it is said to be the first textbook of infectious diseases published in Germany. Professor Jochmann was well qualified for the task as he had had fifteen years' special experience of this—first at Hamburg, then at Breslau, and lastly at the Rudolf Virchow Hospital in Berlin, where he had been director of the infectious diseases department for eight years before his death. The work is divided into four parts. The first deals with those diseases in which infection of the blood is the predominant feature; under this head are included the enteric group, botulism, varieties of septicaemia, including puerperal fever, acute miliary tuberculosis, Malta fever, plague, relapsing fever, malaria, and blackwater fever. The second part is devoted to the discussion of conditions in which the affection of a definite organ or system determines the character of the disease, such as the various forms of sore throat (including diphtheria), mumps, whooping-cough, influenza, tetanus, dysentery, cholera, cerebro-spinal fever, and acute poliomyelitis. In the third part the acute exanthemata are considered, and the fourth part deals with diseases common to man and animals, such as anthrax, glanders, actinomycosis, rabies, foot-and-mouth disease, and trichinosis. An appendix contains a description of methods of disinfection, an enumeration of the infectious diseases notifiable in Prussia, and a short list of the literature (almost exclusively German) on infectious diseases. The work, which is interspersed with numerous excellent illustrations, many of them in colour, will no doubt fill a gap in German literature.

A little book, entitled *Chronicles of an Army Surgeon*,<sup>13</sup> consists of rough diaries in which the author records his experiences of thirty-five years' service in the A.M.D. and R.A.M.C., from 1871 to 1905; of ten years, 1905 to 1915, spent in retirement; and of three years' further home service, 1915 to 1918, during the great war. The diaries seem to have been published as originally jotted down, initials and abbreviations of words being used repeatedly on every page; many of the contractions will probably be unintelligible to a civilian. Had the author, instead of publishing his rough diaries, rewritten the whole in narrative form they might have proved an interesting record of service.

## PREPARATIONS AND APPLIANCES.

### "Soloiz" Urine-Sugar Test Case.

Messrs. BURROUGHS WELLCOME and Co. have put together a very convenient little case of materials for enabling diabetics who are under insulin treatment to keep watch on the sugar reaction of their urine. The reagents used—alkaline citrate and copper sulphate—are in solids. These are dissolved in water which has been heated in a graduated test tube, two of which are supplied in the case. Heat is obtained by burning a solid of hexamethylene-tetramine (hexamine) on a small sheet of asbestos; a solid of this substance will burn for three minutes with a smokeless flame. From a medicine dropper with rubber bulb four drops of urine are added to the solution in the test tube. Gentle boiling for two minutes will reveal the presence of sugar in amounts as low as 0.1 per cent. The case affords a very handy and simple method for testing the presence of sugar in the urine. We are informed that its price to the medical profession is 5s. 5d.

### Cereal Meal.

A cereal food prepared by Messrs. S. Guiterman and Co. (35 and 36, Aldermanbury, London, E.C.2) has been brought to our notice. It contains bran, flax seed, and agar-agar. It is said to act as a corrective of constipation by virtue of the mechanical action of its ingredients, and to be congenial in use because of their demulcent properties. We have examined the product analytically. Its composition agrees with the proprietors' description. Singly, the components have long been known for their specific qualities and have been held in favour in the curative lore of family tradition; being associated together in chosen proportions their beneficial effects may not improbably become enhanced. When cooked according to the directions it yields a porridge which is not unpalatable. A food of this nature deserves to be tried by the public.

## A POSSIBLE METHOD OF INCREASING THE SUPPLY OF BREAD.

BY  
D. NOËL PATON, M.D., LL.D., F.R.S.,  
REGIUS PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF GLASGOW.

In the present state of the country, with its widespread unemployment and poverty, with the cost of living again rising, and with the price of bread again going up, it behoves us to consider very carefully any steps which can be taken to enable the poor more easily to procure the necessary nourishment for themselves and their children. The most important food of the poor man is bread. The position of bread in the national dietary cannot be better stated than in the words of the Food (War) Committee of the Royal Society:

Bread is the prime foodstuff of the working classes, and it is by the consumption of bread that the mass of people are enabled to produce their daily output of work. . . . The poorer the individual or family, the greater is the actual consumption of bread, as well as the proportion it bears to the total dietary. While among the middle classes bread supplies less than one-third of the energy of the total food they consume, with the poorer families of the working classes bread alone has to furnish more than half of the energy of their dietary. Practically no other food is as cheap as bread; that is, no other food generally available will enable a man to do as much work for the money he spends on food as bread will. The poor man is unable to replace deficiencies in bread by other foods, because all other foods he is accustomed to use will cost him more. As a matter of experience it is found that as bread and other foods rise in price, the poor man actually buys more bread than before, because it remains still the cheapest food available to him.

In 1916 the Food Committee pointed out that by raising the standard of milling from 70 to 80 per cent.—as was afterwards done—there would be a gain of 597,000 metric tons of home-produced flour, provided that the amount of wheat remained the same.

A few words of explanation may here be given. At present the object of the miller is to produce a fine white flour which will, when baked, yield a white bread. To secure this he has to eliminate from the wheat as much as possible of everything except the starch-rich endosperm containing the gluten required for forming a dough. This means that only about 70 per cent. of the wheat goes into flour and the remaining 30 per cent. of offal is sold as food for pigs. This contains a large proportion of the proteins, fats, and ash of the grain, and is a material of high nutritive value. The difference between a flour made from the entire grain milled to 100 per cent. and one milled to the usual 70 per cent. is shown in a table given by Sherman.

	Protein.	Fat.	Carbo- hydrate.	Calories per lb.	Ca.	P.
Flour entire ... ..	11.8	1.9	71.9	1630	0.031	0.238
High and medium grade flour	11.4	1.6	75.1	1610	0.02	0.072

The amounts of proteins and fats and the amount of calcium and phosphorus are thus decreased in the finer flours, while the proportion of starch is increased. As regards the bread made from these flours, Sherman gives the following figures:

	Protein.	Fat	Carbo- hydrate.	Calories.	Ca.	P.
Whole wheat ... ..	9.7	0.9	49.7	1113	0.05	0.175
Average white flour ...	9.2	1.3	53.1	1182	0.077	0.093

These figures are somewhat higher than those given by Plimmer on account of the smaller proportion of water. His mean is: Protein 7.2, fat 0.2, carbohydrate 48.1, calories 1036.9. The usual analytical methods for the determination of the fat in breads give unreliable results, as has been shown by Cornack working in the laboratory.

In considering the advantages or disadvantages of raising the standard of milling from 70 to 80 per cent., the Committee had to consider whether it would lead to any serious decrease in the digestibility of the bread. The experiments upon the digestibility of bread then available were very inadequate, and in its calculation the Committee adopted figures which a later and much larger series of experiments showed to be too low. In fact, the result of these later experiments was to indicate that the digestibility of the bread from 80 per cent. flour is as good as that from 70 per cent. flour.

The only loss which has to be considered in this higher grade milling is the offal which is usually fed to pigs, to be used in the form of pork or bacon as human food. As the Committee pointed out, this is a most wasteful method of utilizing the energy of wheat, since the pig uses most of the energy and stores only a small proportion in its body, while a man can use about 96 per cent. of the energy in bread. Hence bread is a much more economical source of energy than pork or bacon. An addition of nearly 10 per cent. to the bread supply of the country would undoubtedly reduce the price.

The Food Committee further considered the question of the possibility of a still higher standard of milling—to 90 per cent. It found that the bread prepared from such flour was "light brown in colour and had a slight flavour of bran." It was quite palatable. In order to determine the actual gain or loss which the use of such bread would involve, a series of experiments upon its digestibility were carried out in Cambridge, London, and Glasgow, on twelve subjects, varying in age from 17½ to 46. The diet consisted mainly of the bread to be tested—800 grams being consumed daily. Weighed quantities of cheese, butter, potted meat, fruit jelly, milk, sugar with tea or coffee made up the diet. Throughout the experiment these other foods remained unchanged. During ten days bread from flour milled to 80 per cent. was used; the subjects then returned to an ordinary dietary; then for ten days they ate the bread from flour milled to 90 per cent. No such extensive series of experiments upon the digestibility of bread have so far been carried out. The results made independently at the three centres were extraordinarily consistent and gave confidence in their acceptance.

The following table shows the digestibility of the two breads:

	80 per cent. Bread.	90 per cent. Bread.
Energy ... ..	95.14 per cent.	94.5 per cent.
Proteins ... ..	89.4 per cent.	87.5 per cent.

The digestibility was only about 2 per cent. less in the 90 per cent. flour, so that nearly all the gain of 10 per cent.

is available, except again for the loss of offal. Thus, if necessary, an increase of nearly 20 per cent. in the bread supply might be secured.

There is yet another ray in which the insufficient supply of wheat might be supplemented—namely, by admixture of flours made from other cereals—barley, maize, oats, rye, or from soya bean. The most abundant of these in the world's supply is maize, and at the instigation of the Food Committee experiments were carried out upon bread made of wheat flour milled to 80 per cent. with a 20 per cent. admixture of maize flour. These showed that this bread was quite palatable, and that its digestibility was about the same as that of bread made from 80 per cent. wheat flour.

A series of prolonged observations were also made upon the inmates of various institutions, who voluntarily took the bread in place of the despised "war bread" without knowing its nature, and who were generally loud in its praise, many expressing regret that the supply could not be continued. All sorts of symptoms—of course, ascribed to the "war bread"—disappeared under its use!

Although the adoption of the higher standard of milling with or without an admixture of flour prepared from cereals other than wheat would undoubtedly increase the bread supply of the nation and reduce its cost, the vested interests of millers and bakers and the prejudice of the public in favour of whiteness of their bread are probably too powerful to allow of its adoption. The duty of the scientist has been discharged when he has shown how an economy may be effected. It must rest with the people of the country to decide whether it shall be carried out. The medical profession is in a position to give to the public the assurance that they would suffer in no way from the use of breads made from flours prepared as suggested.

*Note.*—The report by the Food (War) Committee of the Royal Society on the Digestibility of Breads, 1918 (3206), may be consulted. As anticipated, the millers have already shown their hand. The *Miller* of January 5th contains one of the familiar protests against any change in the mode of preparing flour.

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

### BRITISH MEDICAL ASSOCIATION EVIDENCE.

At the meeting of the Royal Commission on Lunacy and Mental Disorder on January 14th, the Right Hon. H. P. MACMILLAN, K.C., presiding, the Memorandum of Evidence on behalf of the British Medical Association, which was published in the *SUPPLEMENT* of January 17th (pp. 29-36), was presented by Dr. R. Langdon-Down, who was accompanied at the witness table by Dr. J. W. Bone, Dr. F. H. Edwards, Dr. C. O. Hawthorne, Dr. B. W. G. Masterman, Dr. Christine Murrell, and Sir Jenner Verrall, with Dr. C. Comtenay Lord, Assistant Medical Secretary.

The Chairman said that the Commission had received from the British Medical Association a valuable Memorandum, and the Commission proposed that the Memorandum should be incorporated in its proceedings. He and his colleagues recognized that it was the considered representation of the views of the Association, and they thought it should be preserved in the form in which it had been drawn up, obviously with great care. It was recognized that the Association spoke authoritatively for the profession throughout the country. In paragraph 8 the position with regard to mental disorders was stated in a very useful way. Mental ailments differed from physical ailments in the respect that the former might involve a legal aspect consequent upon the restraint imposed on the liberty of the subject, but there were varieties and degrees of mental ailment which did not necessarily involve restraint. He inferred from the Memorandum that it was the view of the profession that the element of compulsion in the treatment of mental disease was really necessary only in cases where the patient was unwilling to be detained and unable to co-operate in his own treatment, and that the extreme measure of the compulsory order should be the last resort rather than the first. From the evidence there had been a progressive development in the conception of mental disease and its proper treatment, but the profession apparently believed that the time was ripe for a further advance.

Dr. Langdon-Down: It must be admitted that medical knowledge in these matters has tended to lag behind medical advances in other fields, not on account of any neglect on the part of the profession, but due to the circumstances which hedge round this question.

The Chairman: In this matter the lawyers and the doctors are not in their usual conflict, as they are over criminal responsibility, for instance. We are both in pursuit of the best way in which cases can be dealt with with the minimum of interference and the maximum of medical benefit.

A discussion took place on the question of terminology, and the Chairman said that he had been much impressed by the phrase "person of unsound mind," which was the phrase selected by the Association as the best description of the persons concerned. Did the Association desire the expression "asylum," which had unfortunate associations, to be abolished? Dr. Langdon-Down said that the views of his colleagues were not very pronounced on this point; whatever term was chosen would attract to itself unhappy ideas.

The Chairman said that he would like some help on the question of mental deficiency, although this was not strictly within the reference of the Commission. He was puzzled when he read the definition in the Mental Deficiency Act of 1913, for it seemed to him to cover a number of things which might well be called mental disorder. Dr. Langdon-Down said that the unfortunate thing about the Mental Deficiency Act was that it endeavoured to set up a medical classification of these patients. The thing to incorporate in an Act of Parliament was not a scientific classification of mental disorder, but a practicable one.

Sir Humphry Rolleston was doubtful of the term "mental abnormality" which the Association had used at the beginning of its scheme of nomenclature. It seemed to him that "mental disability" was preferable, because "abnormality" did not suggest necessarily a pathological condition. Dr. Langdon-Down said that the governing phrase so far as the matter before them was concerned was one of the two derivations from "mental abnormality"—namely, "mental disorder."

Several questions were asked by the Chairman and Earl Russell about the Association's opinion with regard to judicial investigation into the circumstances of a case before certification. Dr. Langdon-Down said that he and his colleagues did not feel that they could usefully advise the Commission on the duties of the justice.

The Chairman: You are quite right in saying that the legal machinery is not your province, but the welfare of the patient is your province. Certain kinds of judicial investigation would undoubtedly be prejudicial to the patient, and I confess that I view with alarm the procedure of cross-examination in the presence of the patient.

Dr. Langdon-Down: I think it all comes back to the discretion of the justice.

The Chairman: But do you think that in the existing code there are sufficient directions to the justice in the exercise of his discretion?

Dr. Langdon-Down: There are other codes besides the law, and I would rather rely on them and on the public attitude towards this matter than on what the law precisely lays down.

The Chairman: One must remember that this jurisdiction is confined to a body who—I say nothing in their disfavour—are certainly very miscellaneous, and whose capacity is very varied, and many of whom must have little ability for discharging judicial functions.

Dr. Langdon-Down: We are anxious to assist, but we feel that these legal difficulties are beyond our ken.

Sir David Drummond: Would not the difficulty be overcome if special justices were appointed?

Dr. Langdon-Down: We considered that, but we felt that anything which added to the difficulty of getting easy access to the justice would be unfortunate. I would suggest that there should be some method of training justices. This is already done to some extent by the Central Association for Mental Welfare.

The view of the Association that there should be two medical certificates in every case was discussed. The Chairman pointed out that it would involve considerable additional expense.

Dr. Langdon-Down: There might be 15,000 such certificates a year. Does that represent an impossible expenditure? In some cases it is very necessary that there should be two medical certificates, and how are you to make exceptions? I think it is an unreasonable responsibility to put upon the doctor that one certificate should suffice in a given case.

The Chairman: I cannot see why two certificates should be required in a private case and only one in a pauper case. The difficulty in diagnosis does not depend on class distinction.

Dr. Langdon-Down: The distinction belongs to the last century. Two doctors must not consult together in also.

back into the question of this double certificate it is interesting to inquire what it is that people were anxious to guard against. Apparently they feared the possibility of collusion between the doctors for the framing of an opinion which was not their real professional opinion, but had some ulterior object. What would be that object?

Dr. Langdon-Down: It is difficult to say.

The Chairman: Sir Humphry Rolleston has pointed out that the British Medical Association does not support the suggestion that the second certificate should be signed by specially approved practitioners. Do you think there is any necessity for exacting that the medical practitioner on whose evidence the justice proceeds should have some special qualification?

Dr. Langdon-Down: We have very carefully debated that question, and we think not, but we are of opinion that the usual medical attendant should be one of the certifying doctors. If you are going to lay down some distinctive qualification, what is your test to be? Any rigorous test, such as a special qualification in psychological medicine, would add to the difficulties of the situation, because it would restrict the number of men available. Is the specialist going to be a greater safeguard than the general practitioner? Is he more likely to detect insanity? It has been said of the specialist that he is very apt to see the disease in which he specializes. We do not believe in these compartments in the profession.

The Chairman: After all, the giving of a certificate is in a sense an act of diagnosis, and when large issues are involved one would have thought the specialist's diagnosis to be most valuable. When issues of life and death are at stake—as, for example, in a murder case in which the defence of insanity is urged—it is not the general practitioner who is brought in, it is the specialist. The specialist is prone to find his specialty simply because he has seen so many more manifestations of it than the general practitioner has seen, and so he gets into the habit of expecting it to turn up, and he may be right. Does the curriculum of the medical student include a sufficient course of training in this branch of medicine?

Dr. Langdon-Down: I think in most cases, yes; I believe it is a necessary requirement.

The Chairman: One would like to be assured that the existing training of the general practitioner is sufficient to equip him to discharge this duty without specialist training.

Dr. Edwards here gave some account of the compulsory instruction, clinical and theoretical, in insanity, which led the Chairman to remark that apparently the usual course included only twelve theoretical and twelve clinical lectures, which was not what they would call in Scotland a half-course. He asked that information might be furnished to the Commission from the university calendars and elsewhere as to the precise nature and volume of this instruction given and required.

Sir H. Rolleston: Is there not a great difficulty at the present time in getting general practitioners to certify at all?

Dr. Langdon-Down: Not on the ground that they distrust their own capacity, but they are sensible of the risks they run.

The Chairman: In view of recent proceedings in the law courts there may be a tendency on the part of the medical profession to refuse to certify because of the legal consequences of improper certification. The criterion of immunity is that the doctor shall have acted in good faith and with reasonable care. I appreciate the point in the Memorandum as to the question of onus. Is it upon the doctor to prove his good faith and reasonable care, or is it upon the person bringing proceedings to prove that these have not been exercised? I gather that the view of the profession is that the protection is inadequate?

Dr. Langdon-Down: Yes.

The Chairman: Of course, the doctor has no responsibility for the correctness of his diagnosis, only that it shall have been made with skill and care. But you would not have the medical man absolved from answerability for exercising his professional skill in good faith in the matter of these certificates as distinguished from his ordinary responsibility when he diagnoses any case?

Dr. Langdon-Down replied that he thought there was more than one distinction between the two cases. The case of the doctor who gave testimony which might lead to certification was similar to that of a witness in a court of law. Another distinction was that he was submitting the evidence to an outside body, and the outside person was at liberty to call in somebody else. He added that the medical profession had no desire to underestimate the responsibility of the doctor. The profession was ready to run risks, because they were all aware of the great distresses caused in family life by these disorders of the mind. But in the principal evidence (Appendix A, SUPPLEMENT, January 17th, p. 34) the Association had put forward considerations which supported the claim that the certifying practitioner should enjoy the immunities of a witness.

The Chairman: Figure the case of a doctor who is quite reckless in the matter, and has chosen to write down about a patient things which really will not hold water; yet these, presented to the justice, may be most convincing.

Dr. Langdon-Down: You are supposing something worse than carelessness.

The Chairman: Well, take a case which is no more than ordinary carelessness but which, in ordinary practice, would expose the doctor to an action. Is he to be protected against carelessness in the case of insanity when he would not be protected against similar carelessness in the case of diphtheria?

Dr. Langdon-Down: The question at issue is really as to the honesty of the doctor. To prevent unfortunate results in such cases as you have mentioned, of course, there is the initial safeguard of the second certificate.

The Chairman: It ultimately depends upon the reliability of the medical profession. Unless you can trust the professional man concerned, the system will break down. But in asking that the certifying practitioner should enjoy the immunities of a witness you are asking for a considerable alteration in the law. At the same time, if the law as recently interpreted does deter the medical profession from doing their duty then some redress must be accorded, for no one else can perform their functions.

Dr. Langdon-Down: If the law as recently interpreted is to stand it would deter medical men undoubtedly. After the first verdict in the Harnett case the Association office was flooded with letters from practitioners asking for guidance.

The Chairman: It does seem quite wrong that a doctor, because he has played his part in the execution of the law relating to lunacy, should on that account be put in the dock, so to speak, to justify himself, rather than that the person attacking him should have to prove that he had done something wrong. But it is a much greater thing to ask that in this particular professional duty the doctor should have an immunity which would absolve him from all possibility of action. I do not know that we can carry this topic further. We have your views upon it.

A number of questions were then asked on the British Medical Association's proposals with regard to voluntary boarders and temporary boarders. The Chairman asked if the Association approved the general proposals of the Mental Treatment Bill. Dr. Langdon-Down replied that it did, in the main. The Chairman then invited the views of the witness as to the present procedure whereby a person who needed immediate attention on account of his mental condition was taken to the workhouse and thereby became technically a pauper. Dr. Langdon-Down said that his committee had hesitated to recommend anything involving extremely costly measures. The ideal would be to have special receiving houses, but, except in very dense populations, such houses could hardly be maintained when they would receive perhaps only two or three cases a year. Another procedure might be to send such cases directly to the asylum.

The Chairman: In our desire to avoid pauperization may we not jump to the other extreme and run the risk of the stigma of asylum residence?

Dr. Langdon-Down: If the accommodation and arrangement of workhouses were better the objection to these institutions would not be so great.

The Chairman: I cannot but feel that some intermediate institution is the ideal—neither a workhouse nor an asylum. The wards of the ordinary hospital might be used. Why should not the man who has suddenly had a mental attack, perhaps in the street, be taken to St. Thomas's or St. George's, in the same way as a man with a broken leg?

Dr. Langdon-Down: I think that is a thing much to be desired.

The Chairman: If one had a free hand it would be a very attractive proposition to use the general hospital for these cases of mental breakdown. The management of the hospital, of course, might not wish to have these troublesome and possibly rather noisy patients in the general ward, and a separate section would have to be provided. The hospital authorities would also have to be armed with powers of compulsory detention. But there is something very attractive in the idea of utilizing the general hospitals, because this would help to break down the distinction between mental and physical illness.

Dr. Masterson here gave some account of the provision of infirmaries in London, and said that if the stigma could only be removed the accommodation in the larger infirmaries of London for lunatics was just what was wanted.

The Commission had not concluded its examination of the Association's evidence at the usual hour for rising, and it was agreed that the witnesses should again meet the Commission at a later date, the Chairman remarking that he did not want to get through this evidence too quickly because of the many topics presented in the Memorandum which opened up useful discussion.

#### *Allegations of Ill Treatment.*

At the opening of this fortnightly session on the previous day (January 13th) the Chairman announced that the Commission, besides hearing evidence by way of exposition and criticism, had thought it right to undertake the judicial investigation of a few specific cases of alleged wrongful detention or ill treatment selected by the National Society for Lunacy Reform, as illustrative of their general criticism. These cases related, not to matters of opinion, but to specific issues of fact, and serious allegations against particular individuals were involved. The Commissioners had decided that in the hearing of these cases both the persons making the allegations and the persons answering them should give their evidence on oath. While it was obvious that only a small number of test cases could be investigated in detail in this manner, the Commissioners had expressed their willingness to receive and consider statements in writing by any persons who desired to bring before them information that might assist their deliberations, whether relating to particular cases or of a general character.

#### *A London County Mental Hospital.*

Dr. G. F. Barham, Superintendent of the London County Mental Hospital, Claybury, was the next witness. He gave figures relating to the numbers of patients and staff.

At the present time, he said, 2,282 beds were occupied. The nurses were in the proportion of 1 to 4.8 patients. Asked whether there had been any complaints with regard to the treatment of patients by nurses, the witness said that he did not think that during the last two years he had had occasion to suspend any attendant pending investigation. Three years ago he had occasion to inquire into a case of alleged ill treatment, but the evidence was not sufficient to support it. He could only recall one case nurse—had had to be dismissed on account of ill treatment. He could not imagine that a patient could be ill treated and fail to bring his grievance to his (the superintendent's) notice. Many

patients, of course, were unhappy and disgruntled and made groundless complaints constantly. He had letters daily from such patients, frequently desiring to be removed from one ward to another, which was always done, if possible. The Chairman said that the Commission recognized that the duties of nurses in mental asylums were of a peculiarly onerous and difficult character, and many patients were unable to appreciate that things were being done for their own good. The atmosphere was abnormal altogether, and the qualification for such work must be the possession of an equable and placid temperament. The witness said that he favoured to some extent the employment of women nurses on the male side. The influence of a woman in the ward was readily seen; the ward became phasanter and brighter, and women were naturally better nurses than men.

A large part of this evidence concerned the conditions of nursing, service at Claybury and also the occupations and dietaries of the patients. The witness advocated some scheme of co-operation between the mental and general hospitals whereby there could be an interchange of staff from time to time. At present such interchanges must be only voluntary, and the general hospitals were loath in many cases to take nurses from mental hospitals. The Chairman commented on the dietary at Claybury, questioning the arrangement whereby the last meal of the day was at 5 o'clock, with nothing until breakfast next morning unless the patient reserved something from his last meal.

Dr. Barham went on to say that he himself did not necessarily see all fresh patients as soon as they arrived, though one of the doctors did, but he saw every new case within a few days of arrival. Such cases were received into special admission wards, highly staffed. Asked as to the effect on a sensitive and educated patient of association with noisy patients, Dr. Barham said that he had quiet reception rooms, and he would not subject a patient to such an association. Shrieking, however, was much less frequent in a mental hospital than was commonly supposed. He described the treatment undertaken at the hospital, and said that as soon as one of the doctors thought the patient was becoming convalescent his, the speaker's, attention was drawn to him or her, and he gave such patient his personal oversight. It would be very helpful if the administrative functions of the head of such an institution could be separated from the medical functions, but he was strongly convinced that it was impossible. Much of his routine administrative work he was able to delegate. The After-Care Association was of great value in solving the problems attaching to these patients when, on discharge, had no home to go to. In 1924 the number of patients discharged was 124, of whom 126 were discharged recovered, 32 relieved and sent to the care of friends, and 13 on trial. Twelve patients sent out on trial relapsed. He was convinced that a very considerable number of incipient cases, if given early rest and appropriate treatment, would escape certification. Asked about the effect of the stigma attaching to a mental hospital, the witness said that under the clinic system the mental department of a general hospital might come to be known as the "mad ward." Asked by Mr. Micklem whether he thought it wise to have such large establishments as that at Claybury, Dr. Barham said that he hoped that future institutions would not be built so large, though the Claybury hospital was not out of hand. A hospital for about 1,000 patients was more suitable.

#### *The Mental After-Care Association.*

Miss Vickers, secretary of the Mental After-Care Association, gave an account of the history and activities of that body. She said that last year the association was brought into touch with cases from 117 mental institutions, and relieved 1,176 patients. With regard to complaints, speaking as one who had personally interviewed over 7,000 patients, Miss Vickers said that these were few and trivial. Probably not more than 4 per cent. of the patients made complaints, and only a very small proportion of the complaints related to actual ill treatment.

#### *Evidence on Oath.*

On January 17th the Commission held the first of a series of special sittings to take sworn evidence with regard to improper detention or ill treatment in asylums. The witnesses are being brought forward by the National Society for Lunacy Reform. The witness who was examined at this sitting was Mr. Hugh Wilson Holman, who answered questions put to him by Mr. W. Stewart, of the society in question. Counsel for the medical practitioners concerned and for Ticehurst Mental Home were Mr. Dickens, K.C., Mr. Croome Johnson, and Mr. Somerville, the last named instructed by the London and Counties Medical Protection Society.

Mr. Holman's statement was that, following on pneumonia, when he was treated in the house of a doctor, he was wrongly certified and sent to an asylum. He described his unavailing protests to a local magistrate and to the Board of Control. After being more than two months in the asylum he escaped, and was recaptured and placed in the refractory ward. Later he was transferred to Ticehurst, where he had only a cursory examination. He eventually escaped and hid for a fortnight, and afterwards, through his solicitors, took steps to obtain redress. On representation to the Master in Lunacy his estate was released.

Mr. Somerville pointed out that the case of Mr. Holman had been tried at the High Court, and Mr. Justice Sankey had said that not only were the authorities at Ticehurst not negligent, but they would have been negligent had they released the patient, under the circumstances.

The Chairman of the Commission admitted the difficulty of dealing with concrete cases. The Commission would not announce a decision in a particular case, but the evidence adduced would form part of the material on which it would base its report.

## THE SPHINCTERS OF THE ALIMENTARY CANAL.

At the present moment a well known London hospital is enforcing its appeal for public support by illustrating in pictorial fashion the aids which to-day it offers to the diagnosis and treatment of disease compared with those available a hundred years ago. These striking posters are designed to prove to passers-by that the sick are fortunate to be seeking relief in the twentieth rather than in the corresponding period of the nineteenth century. They remind the passing physician also of the debt that medical science owes to the physiologist, the pathologist, the biochemist, and the radiologist.

Two articles which we publish this week exemplify some of the benefits which physiology and radiology respectively have conferred on the study of diseases of the intestines. Dr. Arthur Hurst's address, delivered before the Manchester Medical Society, on the sphincters of the alimentary canal and their clinical significance, is based on physiological researches, which, when applied to clinical medicine, quickly explained certain disorders which could never have been properly understood or intelligently treated through any other manner of approach. Those classical researches of Bayliss and Starling, whereby they proved peristalsis to consist of a co-ordinated reflex—a wave of relaxation followed by a wave of contraction—laid the foundation for the physiological study of disorders due to irregular behaviour of the sphincters situated at the cardiac and pyloric orifices of the stomach, the ileo-caecal junction, and the recto-sigmoidal junction.

For many years anatomists persisted in an obstinate incredulity with regard to the existence of sphincters at the cardiac end of the stomach and at the pelvi-rectal junction, and they encouraged mistaken views about the ileo-colic sphincter, which often is still inaccurately referred to as a "valve." A valve differs fundamentally from a sphincter. The valves of the veins and of the heart are constructed to present an impassable barrier to the backward passage of the blood. The sphincters of the alimentary tract have no such valvular architecture; they have, however, a certain resemblance, in function only, to the safety-valves of high-pressure boilers, which allow of an escape of steam when a dangerous pressure is reached. But this figure of speech gives a very imperfect idea of the function and behaviour of sphincters. When working properly the sphincters of the alimentary tract open in advance of the oncoming wave of peristaltic contraction, and thus permit the passage of food, chyme, or faeces; thereafter they close immediately, but not in such a manner as to forbid all possibility of return should this be necessary in the interest of the organism. Thus, when called upon to act, they encourage onward movement and discourage backward. The swing doors at the threshold of a place of entertainment are opened invitingly by an obliging custodian, but if, after having been tempted inside, the entrant finds the demands of the pay-box beyond

his purse, he may escape by the same route through which he entered, though he is likely to be met with less civility on his return: he will have to push the swing doors back with his own energy.

The essential characteristic of the sphincters as compared with the remainder of the alimentary tract is that the lumen of the bowel is closed at the sphincters, whereas elsewhere it is open or potentially open. This provision of nature confers certain advantages, and these vary slightly at the different sites. Thus, the cardiac sphincter offers an obstacle to the regurgitation of the stomach contents back into the oesophagus, though by no means an insuperable obstacle, as the acts of vomiting and eructation testify. The pyloric sphincter serves to hold the stomach contents, and by its ordered relaxation to ensure their timely evacuation into the duodenum. The ileo-caecal sphincter prevents the too rapid passage of the contents of the ileum into the caecum; it also guards the return of material from the caecum back into the small intestine, but certainly not in the manner which the misapplied term "valve" would suggest, for both Dr. Hurst and Dr. Gilbert Scott give examples of conditions under which material from the colon may re-pass this portal. The pelvi-rectal sphincter checks the forward passage of faeces which collect in the pelvic colon until immediately before defaecation.

Irregular behaviour of any of these sphincters results in grave disturbance to health. At the cardiac orifice of the stomach failure on the part of the sphincter to relax in advance of the contracting wave of peristalsis (achalasia of the cardia) results in an accumulation of food in the oesophagus, leading to hypertrophy of its walls and dilatation of its lumen. Reflex irregularity of the pyloric sphincter follows upon gastric or duodenal ulceration, and may be found also in disease of the gall bladder and appendix. The way in which this irregularity arises and the manner in which it may be relieved are well described in Dr. Hurst's paper. Similarly, reflex achalasia of the ileo-caecal sphincter may be caused by chronic appendicitis, and may lead to ileal stasis. Congenital hypertrophic dilatation of the colon (Hirschsprung's disease) and the megacolon of adults may be due to achalasia of the pelvi-rectal and anal sphincters.

Perhaps it is because the word "sphincter" means something which draws close or binds tight, and therefore occludes, that the conception of a sphincter acting as a pathological obstruction to the forward passage of faeces has taken such deep root in the literature of intestinal stasis. A more critical consideration of their physiological function shows at once that they each render a useful service, which, if dislocated, leads to grave inconvenience if not disease. Except in those cases where the sphincters themselves are the seat of disease, the muscle bands yield before gentle and persistent pressure, and place no true obstruction in the path through the bowel of the food residues.

Dr. Gilbert Scott's paper on the technique of radiological examination of the colon gives an account of the contribution to the study of intestinal disease made by another subsidiary science of medicine. His opening sentence, "The clinical evidence presented in most cases of colonic disease is meagre, variable, and often unreliable," has a contentious ring about it, but it is not followed by the extravagant pretensions for some esoteric system which this type of introduction usually leads us to anticipate. If the conclusions of this radiologist be analysed, we find his claims to be moderate; radiological examination often supplements clinical evidence in a useful way, but can never

supersede it, and frequently has little help to bring. The information which it offers must be weighed by the clinician side by side with facts gleaned from other sources. Thus, in speaking of enteroptosis, Dr. Scott remarks: "Let it be clearly understood that radiologists can only state the position of the various sections, the muscular tone, and the rate at which the contents pass through. The deductions must be left to the physician."

There are three main types of organic lesions of the colon in the diagnosis of which help may be sought from the radiologist—new growth, inflammatory lesion, and diverticulation. Unfortunately, the x-ray oracle cannot be expected to answer the most important question concerning a new growth—namely, is it simple or malignant? Nor are the radiological appearances very reliable in the early stages of a cancer before other signs appear, for Dr. Scott admits that "in the very early stages, while the growth is small, and before it encircles the whole lumen of the gut, detection is difficult." Radiological examination has its greatest field of service in the diagnosis of tumours of those regions of the colon which are beyond the reach of the sigmoidoscope.

In such inflammatory diseases as tuberculosis and chronic ulcerative colitis x-ray examination may occasionally add to that "meagre" stock of evidence which Dr. Scott considers the physician may draw from the clinical store, but it is only in exceptional cases that he is greatly enriched by the radiological contribution. On the other hand, in the diagnosis of diverticulation the radiologist has a much more important office, almost indispensable. The way in which the opaque enema method may be used for the diagnosis of this deformity—a commoner one than formerly supposed—is well described in Dr. Scott's paper. It is important to bear in mind that diverticulation of the colon does not necessarily lead to illness; it is only when these little pouches become inflamed or obstructed that they cause trouble. It appears that the opaque enema method has many advantages over the opaque meal given by the mouth in the diagnosis of diseases of the colon, and deserves a greater popularity.

### PHYSICAL TESTS FOR MOTORISTS.

In the United States—no less, perhaps even more, than in this country—there is much concern about the increase in the number of casualties due to motor cars, but in neither country does it seem to be known how far the increase is out of proportion to the change in the conditions of traffic brought about by the popularization of the motor car. The American Medical Association, at its annual meeting in Chicago last June, had before it a report of a committee appointed to consider the adoption of physical standards for drivers of motor vehicles. The report<sup>1</sup> was read to the Section of Ophthalmology, but it is significant that in considering the subject and making recommendations the committee went far beyond the question of eyesight. It dealt also with defects of the limbs, with hearing, with the action of the heart, and with the mentality of the applicant for a licence to drive.

The committee was evidently greatly impressed by the present state of things. It began by expressing the opinion that "the appalling increase in the number of casualties from motor vehicles throughout the United States makes it imperative that everything possible be done to lessen this evil." The members describe

themselves as "physicians cognizant of the harm that may arise from the operation of such vehicles by those physically unfit for such a dangerous operation." The committee urged the medical profession in the United States to "insist on the passage of laws in each State with a view to restricting the granting of licences to such persons as may submit themselves to physical tests at the hands of properly qualified medical practitioners."

In the opinion of the committee, every driver of a motor vehicle should be required to produce to the motor licensing board a certificate showing: (a) that he has no disqualifying defects of either legs or arms; (b) that his vision is at least 20/50 in one eye and at least 20/100 in the other, with or without glasses; (c) that he has not double vision; (d) that he can hear a low spoken voice at 5 ft.; (e) that his "mentality is adequate," and his "heart's action reasonably healthy." It was proposed that the licence should be renewable annually, but that a new medical certificate should be required only every three years, the applicant making a sworn statement in the intervening years that to the best of his knowledge there had been no change in his physical condition. The applicant should pay the cost of his medical examination, the amount being fixed by the motor board in each State. The committee thought it desirable that tests for sight and hearing should be made by ophthalmologists and aurists, and for the other parts of the body by "internists" and surgeons; but it was decided that such specialization was impossible because of the vast number of applicants for licences, and the need for simplicity in tests and reasonable cost to the would-be driver. As "it goes without saying that each examiner must consider himself bound in honour to adhere implicitly to the dictum of the standards," the committee goes on to say that there must be no deviation therefrom at the importunity of the candidate. But (it continues) the doubts and difficulties of examiners would be relieved by the appointment in each county of each State of a board of physical licensure, composed of two general practitioners or surgeons and one ophthalmologist, which should meet at stated intervals and have the final decision in all cases. The fees of the members of these boards also should be paid by the applicants, unless salaried officers should be appointed by the State departments.

The committee thought that some people might regard the visual tests as insufficient, and might think that colour blindness should disqualify. But the committee came to the conclusion that it was the minimum amount of sight with which a motor vehicle could be driven with safety which needed to be determined, and it adopted a degree similar to that used as a standard for soldiers. Insistence on a visual field test was undesirable, and it was doubtful whether general practitioners and surgeons could be depended on to make such a test with sufficient accuracy. Colour blindness would disqualify 3 per cent. of all males, with the result, the committee thought, that there would be a popular and speedy rejection of all physical tests! However, the committee consoled itself with the thought that even the colour-blind person would probably be conscious of the difference in intensity of a red tail light as compared with a white light, and that no harm might be done. In fact, the committee felt that in order to ensure universal adoption of a physical test it would be a mistake to demand too much of either applicant or examiner. Therefore it insisted on simplicity and the avoidance of unessentials.

<sup>1</sup> Journal of the American Medical Association, December 27th, 1924, p. 2094.

The report was drawn up evidently by men who were earnest in the cause of public safety and experts in their own branch of practice. On the other hand, it would appear that none of them can have been expert on the other side of the question—motor driving; and their earnestness would seem to have led them astray from the paths of common sense. Such men, when faced with a difficulty, are always liable to shirk the issue by calling upon the State to increase bureaucratic control, regardless of arguments on the possible futility and costliness of the procedure. Nevertheless, as the dangers of the streets are becoming urgent in this country as well as in the United States, and as changes of varying utility and comfort frequently result from the persistent agitation of enthusiasts, it is well to examine carefully the proposals of the American committee, and to discuss the lines upon which the dangers of the public can be lessened. The standards of efficiency proposed by the committee appear to be very sketchy, and some dangerous conditions in motor drivers seem to have been overlooked. No doubt in a "dry" country it would be improper to suggest the danger of alcoholism, notwithstanding the committee's exclusion of double vision in a driver; but in this country quite a number of accidents occur through drunken drivers. How is a medical examination to exclude a tendency to alcoholic excess or an inability to "carry" even a small amount of liquor? Again, which of the standards suggested by the committee covers the existence of epilepsy in the applicant; and unless the examiner observes an actual fit, can he exclude the possibility of its occurrence? It is doubtful whether it is possible to define a disqualifying defect of legs or arms. We have known a driver, one of whose arms was crippled by infantile paralysis, who was quite able to drive at Brooklands; and with mechanical aids a leg can be dispensed with. Whether hearing is necessary in a driver must depend upon his other senses, such as vision, and upon his care in driving. A standard of vision can be no easy matter. It is not the distance at which test type is read that is important, but the rapidity with which an obstruction can be recognized. Many people with normal vision may almost be said to suffer from partial night-blindness when driving in the dark. Mental adequacy for driving is surely quite impossible to define; and a phrase such as "heart's action reasonably healthy" can only have been dictated by inability to lay down a standard. We cannot help thinking that the proposal for a compulsory medical examination of all motor drivers is impracticable. It is hardly possible to lay down any satisfactory standard; comparatively few people could be ruled out under any kind of physical examination; the physical test would miss some of the more likely causes of danger to the public, such as epilepsy and alcoholism; the variability of standard in the hands of a host of examiners would lead to frequent complaints of injustice; and the numbers of people required to submit themselves to periodic medical examination—there must be between a million and a million and a half licensed drivers in this country—would render examination of any real value almost an impossibility.

But the danger exists, and those who suffer from it are entitled to ask what can be done to reduce it. It may be that the difficulties of the matter are such that the simplest solution is, not to ask the Government to assume further control over the lives and activities of citizens, but to urge a return to one of the more primitive functions of government—that of punishing the wrong-doer. If it were an offence for any person

to drive a motor vehicle when unfit to do so, the onus of proving his fitness would be placed on any driver who endangered the lives of others and by his conduct suggested that he was not fit. In this way the plea of neurasthenia and shell shock, which is so often raised when drivers are summoned for being drunk while driving, would be eliminated. For the neurasthenic is as little entitled to undertake what the American committee describes as the "dangerous operation" of driving a motor vehicle as is the alcoholic or the epileptic. The millennial eliminator of all human troubles will doubtless describe this solution as mere passivity, and will call attention to the sufferings of those who are damaged before the unfit is brought to book. But it is, in our opinion, doubtful whether better results would be obtained by more active measures; and our solution seems at least more likely to foster a spirit of independence and self-reliance in the community. It might not be a bad thing, however, to require from every applicant for the issue or renewal of a driving licence a signed declaration that to the best of his belief he has no defect or disease which makes him unfitted to drive a car or motor cycle. This would indicate upon whose shoulders the legal burden rested.

#### R.A.M.C. MEMORIAL ROLL.

Very nearly a year ago we gave an account of the pages of the Golden Book, or Memorial Roll, of the Royal Army Medical Corps, then on view at the Victoria and Albert Museum, South Kensington. The 270 pages of lambskin containing the names of the officers and men of the R.A.M.C. who fell in the war of 1914-19 have now been bound, and the folio will shortly be deposited in the Chapter House of Westminster Abbey. The writing and illumination are the work of Mr. Graily Hewitt and his six assistants. The Roll is alphabetical; the names are in black lettering, the rank and the date of death in red; initial letters in gold indicate distinctions won. Illuminated sentences from the parable of the Good Samaritan, at the beginning of each alphabetical division, link together the whole design. We have now received from Major-General C. E. Pollock, C.B., C.B.E., D.S.O., honorary secretary of the R.A.M.C. War Memorial Fund, a copy of the printed *Roll of Honour* which has been prepared for the relatives and friends of those whose names are inscribed in the Golden Book, numbering 743 officers and 6,130 warrant officers, non-commissioned officers, and men. Following the arrangement of the original manuscript, the names and brief particulars are printed in alphabetical order. The many Territorial, and temporarily commissioned medical officers are indicated thus: (T.F.) and (Tp.). These and such other abbreviations as "k-in-a" and "d-of-w" for killed in action and died of wounds, though self-explanatory, might perhaps with advantage have been explained in a note at the beginning or end of the volume. The printing, carried out by the Chiswick Press, is good and clear on substantial paper, and the black and red typography of the title page forms an excellent example of the printer's art. We like also the simple binding of dark blue, with lettering and R.A.M.C. crest in gold. The two illustrations, reproducing in black-and-white the title page and a single sheet, give a very imperfect idea of the beauty of the original work. General Pollock asks us to state that the volume can be obtained from Charles Whittingham and Griggs, Ltd., 20, Took's Court, Chancery Lane, E.C.4, or at the bookstall, Westminster Abbey. It is being sold below cost price at 2s. 6d. in order to place it within the reach of everyone. Single copies will be sent by post on receipt of an addressed

label and sixpence for postage; parcels of twelve will be sent carriage free. Many of our readers will undoubtedly wish to possess copies of this *Roll of Honour*.

#### GOLD TREATMENT OF TUBERCULOSIS.

WE have already on two occasions (November 8th, 1924, p. 870, and November 22nd, 1924, p. 961) given particulars with regard to Professor Holger Moellgaard's new method of treating tuberculosis. The well known difficulty of securing penetration of the lipid envelope of the tubercle bacillus is thought to have been solved by "sanoerysin," which is described as an inorganic compound of gold and sodium. It is believed to combine with the bacilli, and so to render possible the bactericidal action of the gold component. Intravenous injection has been recommended, but intramuscular injection has also been found suitable. The sanoerysin appears to remain in the body for four to six days after injection, and to be capable of bactericidal activity to the end of this period. From the results of experiments on animals, Moellgaard believes that the remedy has no bad effect on the blood vessels, the blood corpuscles, or on the organs of the body. Blood pressure and respiration were not affected, and the kidneys were injured only if large doses were suddenly administered. Reactions occurred when the remedy was injected into tuberculous animals, and Moellgaard's next step was the preparation of a serum containing antidotes to these reactions but not interfering with the bactericidal effects. Dr. Secher of the Bispebjerg Hospital, Copenhagen, has given an account of nearly 300 patients in various stages of the disease, and has discussed the dose which should be used in man. The treatment, he says, is not agreeable, but by means of it the duration of lesser degrees of tuberculosis was much shortened, and in the more chronic cases good results were obtained if there remained a sufficient amount of tissue with vital energy. In some cases of rapid phthisis complete arrest resulted, and this happened also in some cases of miliary tuberculosis. Dr. Secher uttered the warning that in these more severe forms of tuberculosis the treatment was always extremely dangerous; it provided a last chance for the patient which might fail, and in that event might accelerate death. Early cases of glandular and pulmonary tuberculosis in children were treated with excellent results, but the later stages were less amenable. Local application of the remedy in surgical tuberculosis had proved beneficial. It is reported that special laboratories for the production of sanoerysin have been established under Professor Moellgaard's direction, and that he has transferred the right of production to a company termed "The Danish Chemo-Therapeutic Company," with a factory and laboratories in Copenhagen. The whole of the manufacture, from the solution of gold in acid to the packing of the sanoerysin powder in small sealed glass vessels, is performed under strict aseptic conditions. For the supply of the British Isles and of all countries outside Europe the company is arranging to co-operate with Messrs. Parke, Davis and Co., of London and Detroit. Issues in this country are at present limited to a few selected hospital centres at which trials arranged by the Medical Research Council are in progress, and Professor Moellgaard does not propose to make the material available for general use until satisfactory results of these trials have been reported.

#### THE USE OF CINCHONA ALKALOIDS.

THE discussion on the mode of employment of the cinchona alkaloids reported on page 159 is of peculiar interest, because so many different aspects of the subject were considered. As Lieut.-Colonel Gage pointed out, there are two distinct problems involved in the choice of antimalarial

drugs. The first and easier problem is to find the best possible method of treatment for the minority of sufferers from malaria to whom the actual price of the drug is unimportant; while the second and more difficult problem is to find a means to make antimalarial remedies available for those vast populations which live in extreme poverty in malarial districts in the East. This second problem requires the supply of large quantities of an efficient drug at the lowest possible price. Catering for the needs of the first and smaller class is naturally the more attractive commercial proposition, and up till now the aim of the planters has been to grow trees whose bark will yield the maximum amount of quinine. It appears possible, however, that a cheaper but equally efficient remedy might be obtained by growing trees whose bark would yield less quinine but a larger amount of total mixed alkaloids than those species of trees which are chiefly planted at present. Apart from the question of cost, the problem as to which is the best possible preparation cannot be regarded as finally settled, since Acton concluded that quinine was less effective than the dextro-rotatory alkaloids in cases of benign tertian fever, and the amorphous alkaloids have been highly commended by various workers. The cinchona alkaloids are required on such a vast scale that it is really an urgent imperial problem to answer the questions set out above as accurately as possible. As Lieut.-Colonel Clayton Lane pointed out, what we need is accurate knowledge of the manner in which the cinchona alkaloids kill malaria parasites. At present we know that when these alkaloids are given in adequate doses the malaria parasite disappears from the blood, and in favourable cases is eradicated from the body; but this represents nearly the whole of our essential knowledge. We do not know whether the drugs kill the parasites directly or by some secondary action; we do not know whether the parasites are killed in the intracorporeal or the extracorporeal stage; and, finally, we do not know whether the intensity of the action depends on the maximum concentration of drug produced in the blood or on the length of time during which the drug is present in the blood. There are a dozen problems which need solving, and which can only be solved by systematic pharmacological and biochemical research. The need for establishing therapeutics on a firm scientific basis was well exemplified by the tragic history referred to by Sir Leonard Rogers. The hasty and inaccurate conclusions drawn by one writer a hundred years ago as to the effects of cinchona sufficed to overthrow a perfectly sound therapeutic treatment of malaria, and to substitute for forty years a practice which was homicidal in its results. The obvious need is for a combined research organized on a large scale to ascertain as exactly and as carefully as is possible the mode of action and comparative efficiency of the cinchona alkaloids. Only when such information is available will it be possible to state with confidence the best policy to be followed in regard to the production of these drugs.

#### TOXIN-ANTITOXIN AND ANATOXIN.

THE use of toxin-antitoxin in antidiphtherial inoculation has sometimes been accompanied by severe reactions, and in our issue of December 6th, 1924 (p. 1064), we drew attention to the work of G. Ramon at the Pasteur Institute, where he has prepared a new product termed "anatoxin," which he believes to be both efficient and innocuous as an antigen. Ramon has now published a detailed account of his investigations.<sup>1</sup> He found that when antidiphtherial serum was added in varying proportions to diphtheria toxin a gradually increasing opalescence appeared, and after a few hours at ordinary room temperature a definite flocculation became evident. This flocculation invariably appeared

<sup>1</sup> *Paris Medical*, December 6th, 1924, p. 480.

first in the tube in which toxin and antitoxin most nearly neutralized each other; and, according to him, it is a specific reaction depending on the interaction of an antigen and its antibody. Ramon found, moreover, that a toxin which had lost some of its toxicity by exposure at room temperature or other means might still retain its flocculating properties unimpaired. In the course of immunizing a series of horses for the production of antidiphtherial serum, Ramon realized that the antigenic value of a toxin did not depend on its toxicity, but was in close relation with its power of flocculation. This would appear to be a point of considerable practical importance, for it not only led directly to the discovery of Ramon's "anatoxin," but also established a simple means of titrating *in vitro* an antigen or its antibody. He found that the less "anatoxin" required to cause flocculation in a given quantity of antiserum, the greater was the antigenic power of that "anatoxin." By adding three or four parts of formol to 1,000 parts of diphtheria toxin and incubating the mixture at 40° C. for one month, he discovered that the toxicity of the product had almost disappeared, while its flocculating and antigenic powers were unaltered. To this new product he gave the term "anatoxin." Other methods of producing "anatoxins" have been devised, but this is the quickest and most certain. Ramon describes diphtheria "anatoxin" as being a stable substance, unaffected by a temperature of 70° C., or by being kept for twelve months in an ice-chest or at room temperature. For prophylaxis two injections of 0.5 c.cm. and 1 c.cm., at an interval of eight to fifteen days, produced immunity in 90 to 95 per cent. of his cases in five to six weeks, and in 100 per cent. in two months. The optimum age for human immunization is given as 2 to 5 years, and it is believed that in the majority of cases the immunity will persist throughout life. For therapeutic purposes Ramon thinks that "anatoxin" may be preferably mixed with antitoxin; its value was most evident in the treatment of carriers, and in the prevention of the sequelae or late complications of diphtheria. It permits of the hyperimmunization of horses. Serums of higher titre were obtained with considerable economy of time and material, and with no risk to the animal. Dujardin-Beaumetz and Mallerbe are reported to have had encouraging results in the treatment of ozaena with diphtheria "anatoxin" used in a similar way. Working on the same lines Descombes has produced a tetanus "anatoxin." The special value of this latter "anatoxin" will probably be prophylactic for man and animals, and an excellent antiserum appears to have been obtained by immunizing horses with it. Weinberg and his co-workers have similarly converted *botulinus* toxin and the toxin of gas gangrene into their corresponding "anatoxins," and with them have obtained from horses antisera of high titre. Ramon is at present working with Dumas in the preparation of a dysentery "anatoxin" and an "anatoxin" for abrin and cobra venenes.

#### THE FOUNDER OF THE IRISH COLLEGE OF PHYSICIANS.

To celebrate the three hundredth anniversary of the birth of John Stearne (1624-1669), the Royal College of Physicians of Ireland held a reception on November 26th last and listened to a scholarly address<sup>1</sup> of great literary distinction dealing with their pious founder's life and activities delivered by the Registrar, whose numerous essays on the same lines mark him out as the author to provide us with a complete history of the Irish College of Physicians, as a companion volume to his *History of the Medical Teaching*

<sup>1</sup> John Stearne, M. and J.U.D. An Address delivered in the Royal College of Physicians of Ireland on the Three Hundredth Anniversary of his Birth, November 26th, 1924, by T. Percy C. Kirkpatrick, M.D., D.Litt., Fellow and Registrar, R.C.P.I. Dublin: Printed at the University Press, 1925. (Pp. 23; 1 plate.)

in Trinity College, Dublin, and of the School of Physic in Ireland (1912). His address recalls another on the same subject given by Dr. Mahaffy on the occasion of the bicentenary (June, 1912) of Trinity College, and it may therefore truly be said that Stearne has been fortunate in his biographers—T. W. Belcher (1865), Mahaffy, and T. Percy C. Kirkpatrick. Stearne entered Trinity College at the tender age of 14½ years, and became a scholar in 1641; but the times became so troublous that the Provost sought refuge in England, and among others Stearne followed his example; in 1642 he entered Sidney Sussex College, Cambridge, where he almost immediately took the B.A. degree, proceeding to the M.A. in 1646; in the intervening four years, the happiest part of his life, he probably read deeply in classics, the philosophical works of the ancient fathers of the Church, and medicine. Francis Glisson was Regius Professor of Physic (1637-1677); Wharton of Pembroke and the *Adenographia* and George Ent of his own college were then associated with the University. About 1649 the times again obliged him to move, and on this occasion he went to Oxford, where he turned in his distress first to Stoic philosophy and then to peace in Bedfordshire. But in 1651 he was admitted a Fellow of Trinity College, Dublin, becoming a Senior Fellow in the next year and professor of Hebrew in 1656; as he was also professor of medicine and perhaps lectured on law, he is a typical example of the all-round excellence of a Fellow of Trinity. His seventeen years of residence were extremely busy and saw much productive work; he wrote six books in Latin, all on philosophico-theological subjects and not dealing primarily with medicine; his erudition was great, but originality—in those days a dangerous property—was not obvious in his writings. As a medical practitioner he followed Hippocrates rather than Galen, being an ardent supporter of physical therapeutics, and an enthusiastic advocate of the use of cold water, tobacco (chiefly by chewing), opium, and the smell of freshly dug earth, which, Dr. Kirkpatrick slyly adds, may also "explain the benefit which some golfers believe that they obtain from the pursuit of the game." In 1661 Stearne set about founding the College of Physicians, obtaining a Royal Charter from Charles II in 1667, and was nominated President for life.

#### THE DRAMA IN CIVILIZED LIFE.

At the social evening of the Royal Society of Medicine last Monday evening, January 19th, Miss Lena Ashwell (Lady Simon) addressed a large audience of Fellows and their guests on the subject of "The drama as a necessity of civilized life." Introducing Miss Ashwell, the President of the society, Sir St. Clair Thomson, described the arts as holding the same position in mental well-being as vitamins held in relation to bodily health. Miss Ashwell's address was an able development of this theme. During the late war the national importance of the drama was recognized, though tardily, by the military authorities, and she had herself been authorized to organize concert parties, which went to France, Egypt, Palestine, and other areas. The success of these parties afforded a proof of the real interest taken by the mass of the population of this country in the drama, yet the theatre was now rapidly losing ground to its unworthy competitor, the cinema. While this country possessed the richest dramatic literature of any nation since the time of the ancient Greeks, it was only rarely that good plays could be seen even in the large provincial centres. This was partly due to the taxation of the theatre as a luxury, so that good plays were generally attended by financial loss to those producing them. It would be a national calamity if the drama were allowed to die out in this country, and its place taken by films of transatlantic origin, the influence of which was often

deplorable on account of the unreal and vicious aspects of life which they portrayed. During the evening Sir T. M. Legge exhibited several specimens of fifteenth-century stained glass recovered from a scrap-heap. These had evidently come from a church in East Anglia, and the faces of saints and the Madonna had been iconoclastically defaced in Cromwellian days. Similar glass was to be seen in the Church of St. Peter Mancroft, Norwich.

#### "E.R.A."

A VERBATIM report will be found at page 179 of a joint meeting of the Sections of Medicine and Electro-Therapeutics of the Royal Society of Medicine, to which Sir Thomas Horder communicated the results so far obtained from an investigation, conducted by a small committee of which he was chairman, into the electronic reactions of Abrams, with special reference to the emanometer of Boyd. The full text of this committee's preliminary report, advance slips of which we have seen by the courtesy of Sir Thomas Horder and Dr. Heald, is accompanied by two appendices containing reports of experiments made chiefly at Glasgow with Dr. E. W. Boyd's emanometer. It is a considerably longer document than the address delivered, but the address appears to contain all the essential points. The other members of the committee were Dr. C. B. Heald, medical adviser to the Department of Civil Aviation, Lieut.-Colonel Lefroy of the Air Ministry, Mr. Whately Smith, employed as a physicist by the same Ministry, and Mr. M. D. Hart, employed as a physicist at the War Office. The committee later on had the co-operation of Mr. E. J. Dingwall, M.A., a research officer to the Society of Psychical Research, and was able to command the whole-time services of Mr. Anson, recommended by the authorities of Faraday House as well qualified to undertake original work in experimental physics. After some introductory remarks, Sir Thomas Horder gave a demonstration of lantern slides and apparatus in order to show the conditions under which the investigations were conducted, and then proceeded to his main address, which we print verbatim. Some copies of the full report were made available among the audience, which filled the Barnes Hall of the Royal Society of Medicine; it would appear that certain reporters of lay newspapers secured copies. Judging from the articles published in these newspapers on the day after the meeting and subsequently, the impression they gathered was that the investigations of the committee could be held to justify the continued use of "E.R.A." methods in medical practice. This, however, does not seem to us to be the conclusion that can legitimately be drawn from Sir Thomas Horder's communication. The conclusions arrived at by the committee, he said, leave the position of the practising electronist as scientifically unsound and as ethically unjustified as it was before; they give no sanction for the use of "E.R.A." in the diagnosis or in the treatment of disease. What we have for convenience termed "the full report" contained a criticism of this JOURNAL which was not embodied by Sir Thomas Horder in his address to the Royal Society of Medicine. The exact status of the full text is not clear to us. The full text, we gather, is to be considered as of the nature of a preliminary communication, and there is as yet no statement that it has been or will be published. We therefore refrain from any comment on this and other sections of the full text, which we must still regard as confidential from our point of view. We cannot undertake to publish replies from individual practitioners of "E.R.A." to the collective communication which has now been received by the Royal Society of Medicine: any reply by them should be a collective reply from some committee or society they recognize as representative of their views.

#### MEDICINE IN JUGO-SLAVIA.

THE last fifty years have seen remarkable progress in the teaching and practice of medicine in some of the associated countries included in the post-war State of Jugo-Slavia. After a long period of lethargy, due to social and political reasons, the national life of Croatia began to awake, and numerous literary and social societies were established between 1860 and 1870. In 1874 the Croat University at Zagreb was founded, and included among its more important scientific societies was the Medical Association of Croatia and Slavonia. For the last fifty years this association has been the centre of medical science in the country, and its activities have given birth to much hygienic legislation and progress in knowledge. The association was from the start the sole representative organization of medical practitioners in the two countries. Various congresses have been held dealing with a large variety of subjects, and in 1877 the official journal of the association, the *Liječnicki Vjesnik*, appeared for the first time. One of the first aims of the association was the organization of a faculty of medicine at the Croat University of Zagreb—an ideal realized in 1917. In 1923 the association created a body to deal with the many and varied social interests of its members. The jubilee of the foundation of the association occurred last year; in connexion with this the *Liječnicki Vjesnik* has published a special commemorative number, which includes sixteen medical contributions in English, French, or German. The general intention of this special number is to demonstrate the present position of the various departments of medicine in Jugo-Slavia.

#### INFLUENZA.

THE deaths attributed to influenza are becoming more numerous. In the week ending January 10th, 124 were registered in the great towns—an increase of 24 over the return of the previous seven days. No city but London, with 28, recorded more than 10 deaths, but Bolton returned 9, Manchester 6, and Salford 5. Twelve months ago there was a similar increase, and there is no reason to apprehend that the present re-emergence is a formidable one. Clinically there has been a good deal of "influenza" this autumn, but, we understand, of mild type. Cases of tonsillitis seem to have been very numerous in some London suburbs.

#### THE HALF-YEARLY INDEXES.

THE usual half-yearly indexes to the JOURNAL and to the SUPPLEMENT and EPILOGUE have been published; they will, however, not be issued with all copies of the JOURNAL, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association, 429, Strand, W.C.2. Those wishing to receive the indexes regularly as published should intimate this desire.

A TELEGRAM from the correspondent of the *Daily Mail* in Melbourne announces that Major-General Sir Neville Howse, V.C., K.C.B., Director of the Australian Army Medical Service, has been appointed Minister of Defence in place of Mr. E. K. Bowden, who has resigned for reasons of health. Sir Neville Howse served in South Africa (1900-2), was P.M.O. to the Australian naval and military expedition to German New Guinea and the Pacific Islands (1914), and was D.M.S. of the Australian Force during the war, including the expedition to the Dardanelles. In 1923 he was Australian representative at the League of Nations Assembly.

## THE ELECTRONIC REACTIONS OF ABRAMS.

COMMUNICATION TO THE ROYAL SOCIETY OF  
MEDICINE BY A COMMITTEE OF WHICH  
SIR THOMAS HORDER IS CHAIRMAN.

A JOINT meeting of the Sections of Medicine and Electro-Therapeutics of the Royal Society of Medicine was held on January 16th, when a preliminary communication concerning the "electronic reactions of Abrams," with special reference to the "emanometer" technique of Boyd, was presented by Sir Thomas Horder. The communication was a report of a small investigating committee consisting of: Sir Thomas Horder; Dr. C. B. Heald, medical adviser to the Director of Civil Aviation; Major H. P. T. Lefroy, head of Wireless Research at the Air Ministry; Mr. M. D. Hart, engaged on physical research on behalf of the War Office; and Mr. Whately Smith, engaged on similar research at the Air Ministry. Sir Thomas Horder acted as chairman of the Committee. Copies of the extremely bulky report, which formed the basis of Sir Thomas Horder's remarks, were distributed to a number of those present.

Dr. ROBERT HUTCHISON (President of the Section of Medicine), who occupied the chair, said that there was some doubt amongst the members of the council of the Section concerned whether Abrams's phenomena were worthy of discussion at all, and that for obvious reasons; but it was finally decided—and he thought rightly—that it would not be becoming of such a society to reject purely on *a priori* grounds a communication which dealt in a perfectly scientific spirit with a set of phenomena which, to say the least, had excited very considerable interest. This was in the nature of a preliminary communication. It was not designed to be complete and final, and therefore it was a question whether it could profitably be followed by any general discussion, which must, if it took place at all, take place on a later date.

### SIR THOMAS HORDER'S INTRODUCTORY REMARKS.

Mr. President, Ladies, and Gentlemen,—In the first place, Dr. Hutchison, I desire, both for myself and my colleagues, to thank you and your fellow members for giving us this opportunity of bringing the communication before you. In affording this opportunity to us you have shown no little courage, since you have risked the censure of those—and they are neither few nor unsubstantial—in whose nostrils this subject has an odour which is quite unavoury. I can only hope, Sir, that you will not regret your decision, but it will rather redound to the credit of both of these important branches of our society.

I spoke of my colleagues, and I hasten to say that I am not standing here this evening on my own behalf. I am here to represent a small committee of investigation, whose joint views I am entrusted to express as adequately as I am able to do. For what I say, therefore—assuming I do not stray too far from the context of the communication which is in fact a report of a committee—I do not accept all the responsibility. By the same token I cannot, even if I wish—and I do not—claim more than one-fifth of any credit which may be due to us. Nor again, if you disapprove of our work, need I feel the onus of more than one-fifth of your censure. The names of this small investigating committee, and their claims to fitness for such work as has been attempted, will be found in the body of the communication, Section 4. I also see that the names appear without detailed qualifications as to fitness on the front page of the galley sheets you have before you. The genesis of this committee is also sketched in the same section, and its varied interests are mentioned. For myself, I have held the honourable chairmanship of the committee, but, apart from this, my own contributions are small in comparison with that of my colleagues. Since three of those are laymen, it fell to either Dr. Heald or to myself to make this communication. My position as chairman made it easy for Dr. Heald to escape the task with which I find myself faced.

I will not take up your time by advancing all the reasons which led us to choose the Royal Society of Medicine as the

body before whom this report should be brought. I will only mention three of those reasons, but I would like to dilate upon the third. In the first place, it is to be noted that it was in the field of medicine that the electronic reactions of Abrams, which I shall call "E.R.A." for short, originated. In the second place, it is common knowledge that the electronic reactions of Abrams have become established as methods of diagnosis and treatment in the practice of a number of registered medical men, even to the exclusion of more recognized methods. Thirdly, we feel strongly that it is high time that the various questions surrounding such practice should be ventilated before an unprejudiced tribunal such as this society; and since neither coaxing nor baiting, nor even sincere invitation, has induced the practising electronists of this country to tell us exactly what they are doing, so that just criticism may be offered on the one hand and justification pleaded on the other, it seems only right that we who are not electronists should ventilate the matter for them. It may be advanced that there is already a Society of Electronists where these questions are debated, but may we not know something of its business, its aims, and its transactions? Is it conceivable that medicine can be advanced by masonic methods of this kind?

Now, there does seem to be a stirring of the waters; to change the metaphor there are signs of a manœuvring for position. Indirectly a plea has been entered for recognition, and an amazing sentence was to be read in a letter from an electronist in a medical journal last week. "Now," he says, "that the subject is receiving a greater measure of consideration than before, it seems only right and fair that the position of genuine Abrams workers in this country should be properly appreciated." We are not offered any definition of what "a genuine Abrams worker" may be. I venture to say that if the definition includes any such notion as seeking after proof with a sense of responsibility to medicine and to the public, it is quite true that no Abrams worker has yet had the appreciation he deserves.

### Demonstration.

Sir Thomas Horder then went on to show on the lantern screen certain diagrams and pictures of the apparatus. The wiring of Abrams's apparatus is shown in Fig. 1, reproduced on this page, and that of the Boyd apparatus in

FIG. 1.—Abrams's Apparatus.

FIG. 2.—Boyd's Apparatus.

Fig. 2. Sir Thomas Horder said he supposed a good many of those present were as ignorant of the Abrams method and technique as was the editor of a certain card, who converted the word "electronic" into "electro-tonic," so that if that editor were present that evening at least one of the audience would start at scratch! Neither

he, nor perhaps his colleagues, were prepared to say that "electro-tonics" might not be as near the truth as "electronic." As a matter of fact, as he thought the audience would conclude at the end of the meeting, they all stood at scratch in regard to this question.

The diagrams showed the series of instruments used in the Abrams technique. They were called—not (Sir Thomas Horder said) that the name appeared to mean anything—the "dynamiser," in which the specimen of blood was placed for examination, the amplifier, and two so-called "reflexophones," from the end of which a flex ran to the forehead of the subject. Another picture showed that, attached to the "dynamiser," there were a couple of metallic contacts connecting with a piece of filter-paper containing the drop of blood, and then, in series with the amplifier, two "reflexophones" with wires to the forehead of the subject. Other lantern slides illustrated the Abrams technique, with the very simple so-called "reflexophones," a single instrument without the amplifier, representing the Abrams method reduced to the simplest possible terms. As to how much simpler these terms might be nobody knew. Ho would forgive those who had been a little flippant about the gadgets connected with this technique, because it was very difficult to be serious; one did not even know whether perhaps the coal-scuttle or a pair of tongs might not replace them, or, in fact, whether any instrument was really necessary at all. Ho handed round in the meeting an example of the so-called "resistance box," which might have been in the hands of the late Albert Abrams himself. There were a number of studs, with a revolving contact-maker, but whether it acted as a resistance box or, as Boyd thought, as an inductance was a matter of dispute.

Another slide showed the interior of one of these "reflexophones" or so-called "resistance boxes." These boxes were sold or leased at very high prices to the early disciples of Abrams, who signed a contract that they would not open the box to see what was in it. Therefore (Sir Thomas said) one might very well compliment Dr. Boyd on his ingenuity in x-raying the instrument from the outside, thus getting a very definite and exact idea of what it contained. Sir Thomas Horder then illustrated various applications of these instruments as introduced in the evolution of the technique in the hands of Dr. W. E. Boyd of Glasgow. One of these was a new experimental coil wound for inductance; Dr. Boyd started with the idea that it really acted as an inductance and not as a resistance at all, and naturally ho constructed his own inductance on scientific lines. The intensity scale, as it was called, was also illustrated on the screen, with the specimen (in this case a chemical substance in a glass bottle) and the so-called "receiving plate," which could be moved nearer to or farther from the specimen. The next picture was the "lay-out" of the Boyd apparatus. As soon as Dr. Boyd discovered that a really essential part of the experiment, in order to get any consistent results at all, was very careful screening of apparatus and subject, and of operator also, he elaborated his apparatus accordingly. Other slides showed the evolution of the technique on the Boyd lines, in respect of the screening, not merely of the apparatus used, but also of the subject and the operator. The effort to replace the human abdomen as a detector, by instruments which could give, by a graph or some other method, an indication of something happening, had hitherto failed. The percussor, therefore, and the percussed were still essential parts of the "lay-out," and the lantern slides showed a boy percussing his colleague with his arms put through a flexible copper gauze screen. Other phases of the experiment were also illustrated. The final picture showed the apparatus in its present form—a form which had been evolved subsequent to the experiments to be described later, and which had not even been seen by his colleagues on the committee.

#### EXPERIMENTS WITH THE APPARATUS.

Sir Thomas Horder then proceeded with the communication proper. He said:  
In proportion to the results obtained, it may be thought that this report is unnecessarily prolix. The present investigators have not found it so simple as might be thought to justify in a few words the important conclusions which they have drawn from their evidence. In his presidential address

before the Pathological Section of this society this year, Professor Clark spoke of the Abrams technique as "one of the most glaring examples of quackery, and said that the claims appear to be of such a nature that their truth or falsehood could be demonstrated in a few hours' test. Well, I shall not offer any apology for so conspicuous an absence of facility on the part of my committee; I will rather content myself with the reflection that it was not for want of experience that our fathers conceived the truth as lying at the bottom of a well, and that much of what lay on the top of it was what Professor Clark calls falsehood.

This communication is concerned with the procedure and results of an investigation of which the object was to determine, as conclusively as might be practicable, whether there be any valid basis for the claims put forward in respect of the so-called "electronic reactions" of Abrams, or of any analogous technique allied thereto or developed therefrom.

The conclusions which have been reached, and the considerations which led to them, will be discussed below, but before proceeding to this main body of the communication four important points must be emphasized. First, it has been found necessary to refer in some detail to certain earlier comments and so-called investigations. For other wise it would have been impossible properly to justify all the views here expressed, adequately to anticipate inevitable criticism, or even to explain the discrepancies between the results of this study and those of previous investigators. Second, it must be clearly understood that this inquiry has been confined exclusively to what may, for convenience, be termed the "diagnostic" aspects of the techniques concerned; that is to say, no attention whatever has been paid to the "oscilloclast" and "electro-bioscope," or to similar contrivances. Third, it is essential that a clear distinction be preserved between these two pieces of apparatus. It is commonly but erroneously supposed that the instrument of Boyd is no more than a minor variation on that of Abrams, whereas it appears actually to be a design de novo based on a different conception of the phenomena involved. Fourth, as will be seen later, certain important experiments were carried out in which homoeopathic drugs happened to be used as test substances. The present investigators wish specifically to emphasize that acceptance of the results of such tests does not involve recognition of principles or clinical methods.

It may also be noted here that for various reasons none of the investigators has himself mastered either of the techniques concerned, so that it has been necessary, as it would in any case have been desirable, to rely for tests and experiments upon the work of exponents who are familiar with them. The investigators wish to take this opportunity of thanking all those who have given demonstrations or collaborated in the work, and of expressing in particular their gratitude to Dr. W. E. Boyd, who has not only given them the fullest facilities for investigation, but has willingly submitted to the imposition of the most rigid control during crucial tests.

I do not propose to overburden this communication, which in any event must be somewhat lengthy, with an extended account of the career of Dr. Abrams, or of the details of his various instruments and methods. Not only are these facts largely irrelevant to the main issue involved, but they are already widely known and reasonably accessible, so that it will be sufficient to record that Abrams was born in 1863, obtained his medical degree at Heidelberg in 1882, practised for many years in San Francisco, founded in 1910 a mode of treatment known as "spondylotherapy," and introduced his so-called "electronic reactions" in 1916. Ho died in 1924.

It is scarcely surprising that claims of this character were in general received both by the medical profession and by lay critics with a scepticism tantamount to hostility. None the less a certain number of practitioners obtained, by sending specimens to Abrams for diagnosis, results which persuaded them that some at least of his claims were not wholly unfounded, and the technique accordingly spread until at the present time there are, it would appear, many hundreds of exponents of his diagnostic and curative methods in the United States of America alone. It is true that of these adherents all too large a proportion are of,

the variety known as "advertising specialists," but there has always been, and still is, a certain reputable minority who, whether they have adhered to the original Abrams apparatus, or, like Dr. Boyd, have devised conspicuous modifications, have sought patiently and sincerely to elucidate the problems involved and to eradicate such errors as they have encountered. This fact, taken in conjunction with the importance of the issues at stake, should have sufficed to ensure for the technique a judicial and painstaking investigation and to save it from the bigoted and *a priori* condemnation in which, actually, critics almost exclusively indulged, and of which alone the majority appear capable.

It would be idle to deny that Dr. Abrams constantly put forward the most startling claims on the slenderest evidence; that he persistently evaded test conditions; that he expressed himself in a jargon characteristic of charlatanism; or that he had no scruple in selling or leasing to others, at high charges, apparatus crudely constructed and at best imperfectly developed. But all this, although indicating an unfortunate lack both of scientific method and of scientific conscience, is no justification of the manner in which the subject has been handled by critics. For the possibility should not have been forgotten that Dr. Abrams might, in fact, have lighted upon a discovery of genuine scientific importance, and yet have elected to exploit it to the utmost for immediate advantage in preference to entering upon a prolonged, laborious, and financially unprofitable research.

Historically, a close parallel may be found in the case of Mesmer, who unquestionably discovered—or rediscovered—phenomena of the utmost interest, but by his thaumaturgic ritual, preposterous terminology, and imperfect methods so vitiated his own case that it was only after many years of labour by such men as Braid, Esdaile, Elliotson, Bernheim, and Charcot that the principles of hypnotism and suggestion were established as scientifically valid. It seems probable that the sequence of events in the present case has been closely similar, and it is at least certain that the methods of criticism hitherto employed have served mainly to create an atmosphere of bitterness and suspicion without contributing in any proportionate degree to the settlement of the issue. It is, indeed, not at all surprising that the ineptitude displayed has so alienated the sympathies of electronic practitioners that they have frequently refused to submit to the "tests"—so called—which have been suggested, although on the other hand their omission, speaking generally, to recognize the limitations of their methods or to suggest fair trials is greatly to be regretted.

Much space has been occupied in various periodicals and elsewhere by articles and commentaries dealing with the Abrams technique, but it is neither necessary nor desirable to consider here more than certain representative examples. Such matter as the sensibly non-committal articles in *Truth*, the eulogies of Mr. Upton Sinclair in *Pearson's*, and the quasi-technical propaganda of the so-called "Electronic Research Laboratories," may legitimately be omitted altogether, for they have no bearing on the fundamental issue as to whether the claims of Abrams have been completely refuted or in some degree substantiated. Such evidence as is available is to be found, rather, in accounts of tests as in the *Scientific American* and in the *Journal of the American Medical Association*, or in the attacks of the *Dearborn Independent* and the *BRITISH MEDICAL JOURNAL*.

In the second category, pride of place must unquestionably be given to the *Scientific American*, the staff of which appear to have been unique in conducting a bona-fide investigation of the merits of the case on a scientific and experimental basis. The responsible committee seems to have made prolonged and sincere efforts to apply fair tests capable of yielding convincing results, but they complain that they have been much hampered by the evasions of electronic practitioners or by their reluctance to submit to experimental control. The results obtained were uniformly negative, and the verdict of the Committee was as follows:

"This Committee finds that the claims advanced on behalf of the electronic reactions of Abrams, and of electronic practice in general, are not substantiated; and it is our belief that they have no basis

in fact. In our opinion the so-called electronic reactions do not occur, and the so-called electronic treatments are without value."

It was, perhaps, unfortunate that the first test undertaken should have consisted in the attempted identification of pure cultures of micro-organisms, for, in spite of the approval of the practitioner concerned, it is at least possible that the technique when applied to diagnosis from specimens of diseased blood operates by virtue, not of the micro-organisms themselves, but of certain products of the interaction which might be lacking in a pure culture. It seems probable also that the Committee might have obtained more positive results if they had concentrated on very simple tests of a "Yes or No" character instead of the more elaborate problem of localizing diseased teeth or the somewhat complex "blood-selection" test described in the issue for June, 1924. It is interesting to note, in this latter connexion, that the results actually obtained were considerably worse than would be expected if pure chance were alone responsible. The Committee appear to have regarded this as specially strong evidence against the technique, whereas it actually suggests that some cause other than chance was operative—that is, that the apparatus was in some fashion working, though not in the way that was intended. Other factors which may have vitiated the experiments will be indicated later.

It should consequently be evident that at the time when the present inquiry was initiated there had arisen a serious need for a more enlightened and searching investigation of electronic techniques than had previously been accorded to them. On the one hand, it was clearly in the public interest that a question of such importance should be settled as speedily and as conclusively as possible; on the other, it was not less clear that the polemical methods so far adopted by the critics and the consequent diffidence displayed by the electronists were calculated indefinitely to retard any such result.

#### *The Prima-facie Evidence.*

I will turn now to the *prima-facie* evidence, with which I will deal somewhat briefly. Reference has been made in the previous section to what may be described as the *prima-facie* evidence—that is to say, to those incidents and evidential items which collectively persuaded the present investigators that the claims of electronic practitioners were not necessarily all ill founded and that the inquiry was, in spite of disappointments, worth pursuing; but it must be understood that it has been collected over a considerable period of time, and that while some parts were obtained before ever serious investigations were initiated, others are of comparatively recent date, and contemporary with certain stages of the fuller research.

It will not be necessary, for the purposes of this section, to describe the many tests and demonstrations which yielded negative results, for it is naturally to be expected that a technique of this kind would fail whenever conditions happened to be unfavourable; whereas the object of the inquiry was to ascertain whether the methods concerned ever yielded successful results which could not reasonably be attributed to pure chance, ingenious guess-work, or deception. It will therefore be sufficient to cite a few of those more successful experiments which encouraged the investigators to believe that delicate, or indeed erratic, as the electronic techniques might be, there still existed some genuine foundation for the claims made on their behalf.

For this purpose three cases of special interest have been selected, mainly on the grounds that they were of a sufficiently concrete nature to admit of reasonably succinct description; but it must be remembered that in addition to these there was encountered from time to time a large amount of more or less impressive evidence albeit of a somewhat indefinite character.

The first notable experiment was conducted in September, 1923, as follows: A certain demonstrator was given six specimens of sputa on filter-papers placed in different envelopes (numbered according to a key by Dr. Heald), and was told that these six specimens constituted three pairs of which one pair was taken from Dr. Heald and another from Dr. C. H. S. Taylor of Cambridge, while the third pair was blank. The problem was to pair the specimens correctly. This the demonstrator successfully achieved, and, in addition, by comparing the "reactions" given by these specimens with those from known specimens, he correctly stated which pair was from Dr. Heald and which from Dr. Taylor. It

is easily seen that the chance of this being effected by accident is equal to  $1/5 \times 1/3 \times 1/2$ , or 1 in 30; for if one specimen be taken to start with, it can be associated as a pair with any of the remaining five, of which alternatives only one will be right; similarly there are three ways in which the remaining four specimens can be paired, while the final discrimination can clearly be done in either of two ways. Thus, then, may be considered a very successful demonstration.

The second experiment to be considered was of a somewhat different character. It will be remembered that in the Royd "emanometer" technique the specimen is carried in a sliding holder, the distance of which from the fixed receiving plate of the instrument can be varied and measured in centimetres on a suitable scale. I have here the actual instrument with the receiving plate, and this gap can be measured accurately. It is claimed that the "intensity" of the "emanation"—of course I cannot read the inverted commas, but by "intensity" we know very little of what is meant, and by "emanation" we know still less, but one has to choose some words in order to get on—can be estimated by noting at what value of this distance the reaction disappears, as the sliding holder is moved away from the receiving plate, or reappears as it is moved towards it. It was considered that if the reactions were of a genuinely physical character it should be possible for the operator correctly to identify the point on the scale at which a specimen began to record (that is, to obtain a reasonably consistent series of "intensity readings") even if the holder were moved by some other person in such a way as to be invisible to him.

Another demonstrator kindly consented to carry out some tests on these lines, and two sets of experiments were accordingly made. The procedure was substantially as follows: the demonstrator, having obtained a satisfactory reaction on some convenient "wave" from the specimen in question, proceeded to determine its "intensity" in the manner indicated above, and the scale reading denoting this "intensity" was recorded. We will say that the specimen is a certain distance from the receiving plate. The experimenter then placed the slider in some other position and, under the demonstrator's direction, moved it nearer to or further from the receiving plate until the demonstrator considered that it was in the same position as before (that is, was showing the original "intensity reading"). The actual position on the scale was then noted and the procedure repeated. Screens were so arranged that the slider was always invisible except to the experimenter, and he took pains to vary its position at the beginning of each trial in an arbitrary fashion and not to afford any clue by his movements, etc., which might be helpful to the demonstrator.

Then follow the records of five of these series. You will see the actual figures in centimetres in which the administrator replaced the specimen after it was displaced by the experimenter.

It is clear that with this form of test it is difficult to assess with precision the chance of the operator obtaining the observed results by accident. It is, however, evident by inspection that the values obtained under test conditions group themselves in every series (except in the third, when the subject was obviously fatigued) reasonably closely around the "correct value" as previously determined by the demonstrator.

The mean error of all trials is 5.78 cm., or, if we exclude cases in which the trial may have been vitiated by the fatigue of the subject, about 4.32 cm. The demonstrator never claimed to work to finer limits than *plus* or *minus* 5 cm., so we can conveniently take this range as a standard. If we consider any test result within 5 cm. of the previously determined intensity as "right," and anything outside this limit as "wrong," we find that the demonstrator obtains twenty-six successes to eighteen failures, or—with the same reservation as before—twenty-three successes to twelve failures. Now the scale is about 55 cm. long, so that the chance of any "test" intensity being, by accident, within 5 cm. of the previously determined value is about two-elevenths. If pure chance alone were at work, therefore, we should expect the demonstrator to produce an average of about two successes in eleven trials, whereas he actually succeeds rather more than six times in eleven according to the less favourable computation, or rather more than seven times on the more favourable.

The last of the definite experiments to be recorded is somewhat similar in type to the foregoing, inasmuch as it was not a matter of diagnosis or of identifying specimens, but of testing a purely technical point which the exponents of the technique regarded as established. It is believed by Dr. Boyd and his colleagues that if an earthed metal plate be interposed between a specimen and the receiving plate of the apparatus, the reactions due to the former will be cut off. That is to say, if the metal plate be placed between them the reaction obtained by the experimenter will cease or disappear. This alleged phenomenon appeared to offer a simple means of testing the physical basis of the technique; for it is easy to arrange a screen of this kind in such a way that its position cannot be directly observed by the demonstrator, who, none the less, should be able to say whether or not it is screening the specimen. The Committee was fortunate in being able again to secure the collaboration of the second demonstrator in these tests.

An earthed metallic screen was arranged so that it could be moved by the experimenter into—or away from—its effective position without the demonstrator being able to determine the sense from a suitable specimen the experimenter adjusted the screening to one of its alternative positions and asked the demonstrator to say whether the specimens were or were not screened; he repeated the manoeuvre a number of times, varying the "screened" or "unscreened" positions in the usual arbitrary manner.

Four series of tests were carried out. In the first series twelve trials were successful and eight were failures; in the second, ten were successful and two were failures; in the third, eight successful

and four failures; in the fourth, sixteen successful and four failures. Total: forty-six successes and eighteen failures out of sixty-four trials. Actually the chances can be shown to be about 1 in 3,038, or "odds of 3,037 to 1 against."

### The Nature of the Problem.

So much for the *prima-facie* case. I now turn to the nature of the problem.

It is easy to condemn a novel and somewhat fantastic technique on *a priori* grounds, and it is not difficult to establish a *non* discovery—even in the face of hostile criticism—if its phenomena can be easily reproduced and explained in terms of accepted scientific principles. But if in addition to their strangeness the phenomena be erratic and difficult to demonstrate, and if their causes be in a high degree obscure, then special precautions must be taken in order to ensure a convincing outcome for the investigation. This was essentially the position which confronted the present investigators, and it will be desirable to give a few words in explanation of the reasons which determined their plan of action.

The study of such phenomena as the so-called "E.R.A." here considered falls naturally into three distinct phases or aspects which may be referred to as demonstration, explanation, and interpretation respectively. In other words, there arises, first, the question of whether the phenomena under consideration occur at all; second, that of why they occur; and third, that of what significance they may possess.

Now, the first aspect is of paramount importance in the earlier stages of an investigation of this kind; for provided it be shown beyond reasonable doubt that new phenomena exist, there is not likely, in these days, to be any difficulty in ensuring an adequate study of their causes and their significance. But although this be true there is no doubt that a demonstration supported by a reasonable explanation is likely to be more convincing and more readily accepted than a bare asseveration of facts which, however well these may be evidenced, must stand alone on their own merits. It was accordingly decided to conduct, in the first instance, a series of essentially physical experiments in order to determine whether the "reactions" (that is, the changes in the percussion note and the concomitant effects apparent only to the operator) were accompanied by any changes (for example, in the electrical condition of the skin) which could be detected by physical apparatus of an ordinary type. And it was decided also to leave temporarily on one side all questions of the manner or degree in which the reactions, if any, might be correlated with disease or with any other physiological conditions of the persons from whom specimens might have been taken. It was thought that some relatively gross effects—similar, for example, to the change in skin resistance associated with the psychogalvanic reflex—might be discovered, and that these would not only enable the existence of the phenomena to be demonstrated beyond cavil, but would also point the way towards the elucidation of their origin. Even in the event of experiments on these lines yielding negative results, the labour involved would not, it was decided, have been wasted.

It was felt that in order to prosecute to the best advantage that essentially physical branch of the inquiry, to which reference has just been made, it would be desirable to employ the whole-time services of a trained physicist. Accordingly Mr. H. St. G. Anson, who was recommended by the authorities of Faraday House as being exceptionally well qualified to undertake original work in experimental physics, was engaged. Mr. Anson's experiments, conducted partly in London and partly with Dr. Boyd in Glasgow, extended over a period of some five months. It will be sufficient to remark here that his work was concerned chiefly with two main points—namely, first, an attempt to obtain instrumental evidence of some change in the electrical condition of the subject's skin concomitant to the variation of the percussion note, and second, to obtain graphical records of this acoustical phenomenon.

Mr. Anson experimented with a great number of electrometers, voltmeters, rectifiers, amplifiers, and galvanometers in various combinations; but he invariably found that if the sensitivity of the apparatus were relatively small no effects could be detected; while if it were great the

ordinary "skin effects" and changes of potential difference due to percussion were such as to mask completely any effects which might have been produced by the "electronic" reaction proper. These experiments consequently led to entirely indeterminate results, so that any detailed account would be out of place in this context, although it is hoped that they may prove of value in subsequent investigations into the physical nature of the phenomenon which it is hoped to undertake in due course.

### The Crucial Tests.

I now pass to the second phase—the crucial tests.

In view of the negative results obtained from the experiments just mentioned, the investigators decided temporarily to abandon this line of work and to concentrate for a time on the fundamental problem of whether any genuine phenomena occurred at all—without regard to the nature of such physical mechanisms as might be involved. Tests for this purpose, in addition to being as economical as may be practicable—in respect of both time and labour—and capable of reproduction if desired, should conform to the three main requirements following:

- (i) They should give the fairest possible chance to the exponents of the technique.
- (ii) They should anticipate all valid criticism on the score of control.
- (iii) They should be capable of yielding results which leave no room for differences of opinion.

The first of these difficulties demands that no restrictions whatever be laid upon the exponents except such as be necessary to secure the second; in general the simpler tests are preferable to the more elaborate, and the type of test selected should be such as to secure the full approval and confidence of the exponents. In particular, all processes of sterilization of apparatus, special packing of specimens, use of known specimens as controls, together with collaboration by two or more exponents, and any desired amount of retesting or checking, are not only perfectly legitimate but are to be encouraged in the best interests of the test.

In order to satisfy the second condition it is necessary and sufficient so to organize the procedure that the exponents of the technique cannot possibly obtain correct results save by the bona-fide use of the apparatus, or by that operation of pure chance which is covered by the third proviso. In other words, the test conditions must be such as to exclude fraud (whether witting or unwitting) together with self-deception. The precautions adopted by the investigators in this connexion will perhaps be considered excessive in some quarters, and must often have appeared both irksome and superfluous to those who were subjected to them. But apart from deliberate trickery, the literature of psychopathology contains so many cases of elaborate deceptions perpetrated by apparently reputable persons; that no investigation of this kind would be of value in which such possibilities had not received the most careful consideration.

The third condition can only be satisfied by so devising experiments as to yield *quantitative* results. This point is highly important, for it offers the only possibility of avoiding controversy as to the actual value of the results obtained.

In view of these considerations, it was decided to rely exclusively on tests of such a character that the value of the results obtained could be unequivocally computed by mathematical methods, and to persevere with a series of such tests until it became apparent that their general tendency was either towards results reasonably attributable to chance alone or else towards figures which could not rationally be ascribed to such causes.

The first test of this kind was carried out in London in May, 1924, with the co-operation of Dr. W. R. McCrae, assisted by Dr. Boyd. It took the form of an attempt to separate correctly twenty pairs of specimens of sputa taken from two patients chosen and approved by Dr. McCrae. Twenty specimens were taken from each patient by Dr. Heald and Mr. Whately Smith, and were arranged by them in pairs and numbered according to an arbitrary key. Each pair contained one specimen from each patient, but there was nothing to indicate which was which. Control specimens were taken by Dr. McCrae. The outcome of the test was unfavourable to the technique, for of the results returned by the exponents eleven only were correct, while nine were wrong; which is just the kind of result which would be expected if chance alone were operative. In a memorandum addressed to the investigators,

Dr. Boyd ascribed this failure to two main causes—namely, first that the screening arrangements then available at Dr. McCrae's laboratory were insufficient to ensure complete freedom from "contamination," and secondly, that the time required for examining, checking, and rechecking forty specimens was so great that many of them became stale before they could be dealt with—a tendency liable to be aggravated by the necessity for avoiding undue fatigue on the part of operator and subject.

Dr. Boyd also expressed a desire that further tests of a slightly different character, but equally conforming to the requirements of the investigators, should be carried out in his own laboratory at Glasgow. To this suggestion the investigators willingly agreed, and on June 6th, 1924, Mr. Whately Smith visited Glasgow for the purpose. His full report is given in Appendix I, and the following quotation and abbreviated account of the tests is given here merely to show the kind of results obtained and the type of procedure adopted.

The first test consisted in discrimination between two apparently identical substances which were presented by the experimenter (Mr. Whately Smith) in such a way as to be indistinguishable by visual or other normal methods. Of twenty-five successive trials all were successful; the chance of this result being obtained by accident is 1 in 33,554,432.

Mr. Whately Smith says: "After inspecting the laboratory and apparatus the first test was attempted. From a group of about a dozen sterilized bottles and corks I selected two closely similar examples of each. One bottle was filled to a depth of about 1/4 in. with a white granular substance believed to be 'active,' the other to an equal depth with a substance of identically similar appearance alleged to be 'neutral.' The corks were inscribed 'sulphur 10 m.' and 'blank' respectively, in small characters. I satisfied myself by personal trial that it was utterly impossible for either the 'operator' (Colin Campbell) or the 'subject' (James Watson)—two Gallowgate boys—to distinguish the bottles visually when placed in position on the shelf just inside the hatch. This was due to (a) the very dim light illuminating the bottles when in position; (b) the several thicknesses of copper gauze which in each case obscured the view; and (c) the close similarity of the bottles themselves."

I have here a model of the actual laboratory in which these experiments were conducted, and I think it is so constructed that it is Dr. Boyd's laboratory, as it were, with the roof off, and if I turn it up—and you will remember the fact that the roof is now facing you, you will get an idea of the conditions under which these experiments were undertaken. It shows the outer room in which the experimenters stand with various bottles and drugs and sterilizing apparatus at hand. There is a small hatch which is covered by a copper plate running on a pulley. That is the only communication between this outer room and the copper screen or lined compartment in which the operator, the percussor, and the subject are placed. Just inside this small hatch there is a shelf, and the specimen—that is to say, the bottle containing sulphur or containing a substance which is inactive—is placed on that shelf just beyond a sheet of copper so arranged as to prevent any sight on the part of either of these boys of what is happening, as, for instance, which bottle is placed and when it is placed.

The emanometer is standing on a small table, the receiving plate facing the specimen on the shelf; the other end of the emanometer projects under this copper screen so that it can be adjusted or tuned as it were by the left-hand subject, and then we have the arrangement which I showed you on the lantern slide, the boy percussing his colleague with the arms put through the flexible copper gauze. The walls of this small room are covered with sheet copper or copper gauze, there is a copper screen, and a small hole for observation purposes. That is a model of the actual laboratory where these tests were carried out.

Mr. Whately Smith continues: "Dr. Boyd, Miss C. (his secretary), and myself then withdrew to the outer office, and I inserted the two bottles 'S' and 'B' alternately through the hatch until the operator professed himself as satisfied with the tuning and as prepared to discriminate between the two substances."

The tests then proceeded, and Mr. Smith says: "For each trial I raised the sliding panel of the hatch, inserted a bottle, dropped the hatch, and waited for the operator to say whether the reaction obtained was 'dull' (corresponding to the 'active' substance) or 'clear' (corresponding to the 'neutral' substance). The decision was practically always given within a second of dropping the panel; and on several occasions even before I had fully withdrawn my hand; I found it, in fact, difficult to keep pace with the operator. While this was going on, Dr. Boyd and his secretary were, for the greater part of the time, just outside the room in which I was working, but continuously within sight. I was careful to vary the order in which I presented the bottles, and also to shuffle them frequently, so that no possible observation of my movements by operator or subject could furnish any clue as to which bottle would next be presented. After certain trials the operator asked, and was allowed, to check the two substances—that is to say, first the one and then the other was presented, and he was told which was which. After trial 10 the subject went out and washed in order to remove possible contamination."

The fifth and last test was a screening experiment conducted on much the same lines as that already mentioned in an earlier section. Of sixteen trials all were successful, and the chance of this being due to accident or guess-work is 1 in 65,536. We attempted to identify one substance from five others. The chance of these results being achieved by accident was 1 in 7,000 odd. The next one, the screening experiment, which is the crucial test, corresponding to those in that *prima-facie* list which I gave you, was done under much stricter conditions.

Then there is a summary of the success achieved with the chances of accidental success. The drug discrimination gave that a very large probability against the result being accidental. Then the screening experiment shows a still higher probability against chance.

It was quite clear from these figures that the results obtained, whatever their true origin, could not reasonably be ascribed to the operation of chance alone. The only alternative to accepting the apparent phenomena as genuine was to assume either that Mr. Whately Smith's report was grossly inaccurate or else that he himself had been deceived by trickery—possibly pathological—on the part of Dr. Boyd or his assistants. Both these possibilities appeared to the investigators to be exceedingly remote. It was, however, represented that an issue so important as this should not be allowed to depend on the unsupported testimony of any single observer, and the desirability of conducting a repetition of the tests described in order to confirm or refute these results as conclusively as possible was strongly urged. It was further pointed out that although the other investigators could deal adequately with the question of accurate reporting, it would be advisable to enlist expert assistance with respect to the possibility of fraud, on the ground that no one who does not possess specialized knowledge of a high order is competent to express an authoritative opinion on such matters.

The investigators accordingly approached Mr. E. J. Dingwall, M.A., and invited his co-operation in this aspect of the work. Mr. Dingwall is research officer to the Society for Psychical Research, and has made a special study of the methods of deception and prestidigitatory technique associated with such matters as spurious "clairvoyance," "billet reading," "spirit photography," and similar performances in which chicanery is frequently encountered, and of all of which he possesses a world-wide experience. In the opinion of the investigators he represented the highest available authority on the subject, and they considered that although, strictly speaking, the only way of excluding trickery absolutely would be to repeat the tests in person, using specially constructed apparatus and independent subjects, yet if an expert of Mr. Dingwall's calibre failed to detect any suspicious indication, they need feel no further uneasiness on this score, especially in view of the considerable bulk of collateral evidence with which they were already acquainted. Mr. Dingwall kindly consented to act as consultant in this matter, and in due course accompanied Dr. Heald, Mr. Whately Smith, and myself to Glasgow on August 29th, 1924.

A full account of the proceedings on this occasion is given in Appendix II. The tests conducted were substantially identical with those performed by Mr. Whately Smith in the course of his earlier visit, and the degree of success attained by Dr. Boyd was not less impressive. Mr. Dingwall carefully noted the arrangements and procedure and made certain suggestions as regards screening, etc., all of which were duly carried out without reacting in any way adversely on the success of the tests employed. It would therefore appear that, subject only to the theoretical reservation made above, all possibility of deception may safely be regarded as eliminated. The other investigators were entirely satisfied with the conditions of the tests and demonstrations given, and formed the opinion that no more convincing exposition of the reality of the phenomena could reasonably be desired.

I will now pass to the conclusions to which the Committee have been led.

[Sir Thomas Horder then read the following conclusions and "afterword" which appear in the report.]

#### Conclusions.

In view of the general considerations and concrete evidence cited in this paper, the signatories consider that the following conclusions are justified:

(1) That certain substances, when placed in proper relation to the emanometer of Boyd, produce, beyond any reasonable doubt, changes in the abdominal wall of "the subject" of a kind which may be detected by percussion. This is tantamount to the statement that the fundamental proposition underlying, in common, the original and certain other forms of apparatus designed for the purpose of eliciting the so-called electronic reactions of Abrams, is established to a very high degree of probability.

(2) That no evidence justifying this deduction is yet available from the work of those who practise with the apparatus as yet designed by Abrams himself.

(3) That the phenomena appear to be extremely elusive, and highly susceptible to interference, so that in order to obtain reliable results it is necessary to take the most elaborate precautions, particularly as regards the elimination of effects due to irrelevant objects.

(4) That it would be premature at the present time even to hazard in the most tentative manner any hypothesis as to the physical basis of the phenomena here described.

It is impossible to emphasize too strongly that nothing in this Communication is to be taken as implying that any correlation of those changes in the abdominal wall, referred to in Conclusion (1), with pathological conditions has yet been shown, or *a fortiori*, that any justification—physical, pathological, nosological, or clinical—exists for the direct use of either the Abrams or Boyd apparatus in diagnosis or treatment.

#### Afterword: The Bearing of these Conclusions upon Medicine and Medical Practice.

Seeing that the electronic reactions of Abrams had their inception in the field of medicine, this Communication will scarcely be complete without a reference to the question which will immediately be asked by many who read it: "What relevancy have the facts now demonstrated to the diagnosis and treatment of disease?" The electronic practitioner will probably answer, "A great deal"; though he may protest that the demonstration has been entirely redundant; or, less ungracious, he may accept the demonstration as merely helping to establish further the claims he has already made. But in reality the answer must clearly be that the conclusions in this Communication, as they now stand, are not in the slightest degree pertinent to the diagnosis or treatment of disease in any practical sense. That is not to say that they may not possess all sorts of potential bearings upon both of these things. But until the research is taken much further, and until either the explanation, or the significance, of the facts recorded shall be forthcoming, the application of the Communication in the field of medicine is nil. At present there is no known correlation between the phenomena described and the fundamental facts of pathology, so that the value of this Communication to the practising physician can only be negative.

As already stated, the present investigators have concerned themselves solely with the establishment, to their satisfaction, of certain basic facts. In view of the urgent need of an answer to the question "Does anything happen?" they are satisfied for the moment with being able to say in effect, "Something does happen." Both the explanation and the application of the facts established await further investigation. Which of these will come before the other it is impossible to say, but until one of them arrives the mere statement of the phenomena here described gives no sort of sanction to any practitioner for using the Abrams method in practice. He may, of course, find a legitimate sanction elsewhere; for example, he may show results so consistently good as to justify him in continuing to use the Abrams apparatus in his daily work. But there is no evidence that even the most adept exponent obtains results so consistent as to justify him in doing more than experiment privately with the method. The present investigation clearly suggests one reason, and in itself a sufficient reason why the electronist's results cannot but be inconsistent—namely, the absolute necessity for efficient screening as proved by Boyd. That it has not been found by electronists generally that such screening is imperative in order to eliminate errors, is in itself a damning proof that the haste with which the method has been carried into the consulting room has prevented any proper investigation of its limitations or of its potentialities.

It seems probable that such developments as may take place on the clinical side are most likely to proceed from the methods initiated by Dr. Boyd, and still in process of elaboration by him.

\* This word is exclusively used herein to refer to those who rely upon the apparatus and technique as designed by Abrams himself.

By the term "consistent results" is meant not the conformity of the electronist's diagnosis with the clinical and pathological facts of the case—concerning which reference will be made later—but some reasonable degree of conformity as between the results obtained by different electronists working upon the same material; and as between the results obtained at different sittings held by the same electronist, equally working with the same material. But this reasonable degree of conformity has been conspicuously absent in both cases. In the various efforts made by individual members of the present Committee to obtain evidence of "something happening" by submitting tests of a simple kind to electronists willing to co-operate in this fashion—tests which it has not been thought necessary to specify in detail in this Communication—lack of consistency has been very striking. On more than one occasion the electronist has admitted the discrepancies in his own results, and has on this account considered them unreliable and therefore to be disregarded.

There are in the hands of the Committee details of experiments, carefully devised with a view to testing consistency of results, and submitted to exponents of the Abrams method but with conspicuous failure. All account of these experiments has been omitted from this Communication at the express request of the practitioner who was chiefly concerned "pending further research." These belated misgivings may have been prompted by the knowledge of the imminence of a report of experiments carried out in such a way as to yield unimpeachable results. Here was an opportunity for some electronist, from whom the saving grace of the scientific spirit has not wholly departed, to come forward and acknowledge publicly the glaring inconsistencies which inevitably and constantly face him in his daily practice. But the opportunity has been missed. To turn king's evidence is never popular and oftentimes unprofitable.

When electronists have been asked for an explanation of such inconsistencies as those referred to above they have sometimes attributed them to lack of expertness in their use of the method and sometimes to new and startling discoveries as regards fallacies of dimensions so large that their very existence would seem, to any unbiased mind, to throw the whole thing back into the melting pot. But neither the modesty which may be supposed to dictate the first explanation, nor the fallacies referred to in the second, would appear to induce any such hesitation in actual practice. The practising electronist is not in the habit of prefacing his diagnosis by declarations of his own lack of skill, nor by any reference to such confusing facts as (for example) that unknown factors cause the same "reaction" to be given by a carcinoma of the oesophagus and by pulmonary tuberculosis, or by simple gastric ulcer and by cancer of the stomach. No doubt any such prefaces, if systematically adopted, would quickly dispose of electronic practice altogether!

It is obvious, therefore, that there is, at present, no proper sanction for the use of the electronic reactions of Abrams on the ground of consistency of results, whether as between different workers or as between the results obtained by the same worker at different times. But even supposing that such glaring discrepancies can be eliminated by proper attention to technical points such as the screening which Boyd finds so essential, and by the substitution of the Boyd apparatus for that of Abrams, sanction will still be lacking so long as there exists no demonstrable correspondence between the "reactions" found and known pathological states. For patients do not suffer from "reactions"; they suffer from anatomical and physiological disturbances. If it should be claimed by the electronist that the establishment as criteria of his "reactions" is of greater moment to the patient than is the recognition of tissue changes and of the dysfunctions of organs, then the onus lies with the electronist of stating adequate reasons why the whole criteria of disease, as built up by the sciences of morbid anatomy and morbid physiology, should be revolutionized in this manner. This onus has never been accepted.

There is one other thing which may justly be regarded as a condemnation of electronic practice: electronists have

been hard at work for some ten years; they have "diagnosed" and "treated" thousands of patients; yet no contribution to pathology, which is the bed-rock of medicine, has been made by any of them. Surely this is a significant fact, when it is remembered how epoch-making are the claims made on behalf of E.R.A.

To sum up. The conclusions arrived at in this Communication leave the position of the practising electronist as scientifically unsound and as ethically unjustified as it was before. They give no sanction for the use of E.R.A. in the diagnosis or in the treatment of disease. Nor does there appear to be any other sanction for this kind of practice at the present time.

#### CHAIRMAN'S CLOSING REMARKS.

The CHAIRMAN (Dr. Robert Hutchison) said: I should like to thank Sir Thomas Horder in your name for his valuable communication, and particularly for the very lucid way in which he has presented it. As I said at the beginning, it is not proposed to hold a discussion immediately on this Communication; there is hardly time now, even if it were desirable on other grounds. On the other hand, if there is a general desire on the part of those present that at some later date a discussion should take place the officials of the Section will be glad to arrange one. I will therefore ask those who would like a discussion to hold up their hands. (A vote was then taken, and about a dozen hands were held up in favour of continuing the discussion.) There does not appear to be any very urgent desire for a discussion, so I think at the moment we had better leave it unsettled as to whether there should be a discussion or not.

### SMALL-POX IN ENGLAND AND WALES IN 1924.

#### I. PREVALENCE.

The Registrar-General's weekly returns of notifications of infectious diseases covering the year 1924 are now complete. As each year includes one day (and in leap years two days) more than fifty-two weeks, a total of weekly returns never exactly represents a calendar year, and once in a while a year has to be regarded as containing fifty-three weeks so as to include the lost days. That is the case for 1924, which for weekly statistical purposes began on Sunday, December 30th, 1923, and ended on Saturday, January 3rd, 1925.

In the year so defined the total notifications of small-pox were 3,784.

The following are the notification figures for the past fourteen years:

Year.	Cases.	Year.	Cases.
1911	289	1918	63
1912	121	1919	311
1913	113	1920	280
1914	65	1921	336
1915	93	1922	973
1916	159	1923	2,504
1917	7	1924	3,784
	847		8,251

The striking diminution from 1911 to 1917, and the still more striking increase of prevalence since 1917, are shown in this table. In the second seven years the cases are nearly ten times as numerous as in the first.

As regards seasonal distribution the notifications for the four quarters of the two years 1923 and 1924 were:

	1923.	1924.
First quarter	550	1,005
Second quarter	707	1,195
Third quarter	662	643
Fourth quarter	565	943*
Total	2,504	3,784

\* Fourteen weeks.

In 1924 the disease has prevailed chiefly in the Midlands and the North of England. Wales and the southern counties have been practically free from it; Derbyshire, Notts, Northumberland, Cumberland, the North and West Ridings of Yorkshire, and the counties of Gloucester and Leicester have all been involved. In the borough of Chesterfield there were 528 notifications, and in the Chesterfield rural district 218. In the borough the cases were mainly in the first half of the year, the last fourteen weeks having furnished only 19. In the rural area around it, however, the numbers rather increased than diminished in the course of the year. Other rural districts of Derbyshire considerably affected were Blackwell and Swadlincote. The county borough of Derby had no cases in the first quarter of the year, but there were 52 in the second quarter, 45 in the third, and 127 in the remaining fourteen weeks—a total of 222 in the year. The prevalence was very irregular in the latter part of the year, ranging from a single notification in the forty-second week to 37 in the forty-fifth.

Middlesbrough in the North Riding of Yorkshire had 485 cases, and the last fourteen weeks of the year contributed 169 to that total. In Cumberland the boroughs of Workington and Cockermouth had respectively 104 and 67 cases, almost all in the first half of the year. In Northumberland the urban district of Ashington had 301 cases in the fifty-three weeks, mainly in the second and third quarters of the year. In the county of Notts several places, especially Hucknall and Kirkby-in-Ashfield, Basford, and Mansfield, have been attacked. In Coventry some cases occurred, but nothing to call an epidemic developed.

The largest provincial cities in England, say the half-dozen towns with more than 300,000 inhabitants—Birmingham, Liverpool, Manchester, Sheffield, Leeds, and Bristol—with a total population of nearly four million, remain remarkably free from the disease, though they include ports where there is continual risk of introduction of infection. The same remark applies to London. In the third quarter of 1924 there were 3 cases—one each in Chelsea, Kensington, and St. Pancras—but no epidemic resulted. In the same quarter of the year there were 10 cases in Willesden.

### III. FATALITY.

The following is a statement of deaths from small-pox in the fourteen years 1911-24:

Year.	Deaths.	Year.	Deaths.
1911 ... ..	23	1918 ... ..	2
1912 ... ..	9	1919 ... ..	28
1913 ... ..	10	1920 ... ..	30
1914 ... ..	4	1921 ... ..	5
1915 ... ..	13	1922 ... ..	27
1916 ... ..	18	1923 ... ..	7
1917 ... ..	3	1924 ... ..	13
	80		112

The total cases in the fourteen years having been 9,098 and the total deaths 192, the fatality rate was 2.1 per cent. In the last seven years the rate was only 1.3 per cent. These are very low figures compared with earlier times, and even so they are not based entirely on the prevalent mild type of the disease. In Bristol, for example, in 1915 infection introduced from Spain gave rise to an outbreak of 32 cases with 7 deaths. In London, in 1922, of the 27 deaths 20 occurred in an outbreak of 65 cases, including those at the Poplar workhouse, and in the 10 cases at Willesden in 1924 there were 3 deaths.

Without reference to the wide differences between the case mortality of the vaccinated and unvaccinated, or between the mild and severe types of the disease, but taking the whole facts in their broadest aspect, there has been, ever since the European pandemic of 1870-73, a persistent though irregular decline in the death-dealing power of variola. What the future has in store in that respect it is quite impossible to prophesy, or even to guess. There is no good evidence that the mild type is becoming more severe, but rather the contrary. The old small-pox, however, may return any day, and the country must remain ready to meet the situation if it should arise. It is too soon yet to assume that we are rid of the danger.

## England and Wales.

### LEEDS HOSPITALS.

On January 16th Princess Mary visited Leeds for the annual distribution of prizes to the nursing staff of Leeds General Infirmary. In the absence, through illness, of Sir Arthur Stanley, the Vice-Chancellor of the University, Dr. J. B. Baillie, gave an account of the work of the past year, mentioning that three infirmary nurses had qualified as medalists. A four years' course had been recently introduced for nurses in connexion with the Infirmary. Their teachers were professors in the school of medicine, the nurses attended University classes, and the University itself granted the diploma for nursing. No other university gave a diploma to nurses, and this scheme placed nursing on a scientific basis. A contract for £130,000 has now been arranged in connexion with the process of transferring the Leeds War Pensions Hospital from Beckett's Park to Gledhow Grove. A total expenditure of £166,000 was sanctioned, but the cost of completely furnishing the hospital will probably amount to £200,000. The existing mansion on the estate will be preserved for administrative purposes, and new buildings will be erected between it and Harehills Lane. These new buildings will occupy a frontage of almost 600 feet, and will include a one-storied building for twenty officers, and two men's wards, two stories high, each capable of taking sixty-four beds. A recreation hall, 130 feet long, will be built; also a third-ward, a two-storied nurses' home, various workshops, a dispensary, a gymnasium, and kitchens. The buildings will be of brick, with slight stone facing, resembling the new buildings of the Leeds Infirmary.

### A CORONER'S CLASSIFICATION OF HIS INQUESTS.

Addressing a jury recently, Dr. F. J. Waldo, coroner for the City of London and Borough of Southwark, said that during last year he had held 541 inquiries, 48 more than in 1923. He had only dispensed with a jury in 111 "natural deaths." In all death inquests—save 11—he had ordered a full post-mortem examination by a competent medical practitioner, and, in special cases, at the hands of an expert independent pathologist. Among the inquests held were one case of murder and 29 cases of suicide. As most of his cases were drawn from large general hospitals, such as those of St. Bartholomew's and Guy's, a large majority of inquiries held before him were violent as opposed to natural deaths. A record number of 63 public inquiries by a jury (27 in the City and 36 in Southwark) had been held before him into traffic fatalities, as compared with 42 in the previous year. There were only 11 sudden and violent deaths, accelerated by the administration of anaesthetics given for necessary operations—the same number as last year. Of these inquests, 2 were held in the City and 9 in Southwark. There had been a big reduction in the number of inquests held on babies found suffocated in bed with their parents or guardians owing to the want of a cot or cradle. These deaths numbered two only—a record—and in one of these two cases (both in Southwark) there was no room for a cot owing to mother, father, and five girls and boys, ranging in age from 13 years to 3 weeks, having to sleep in one tiny room. Prior to his entering office in 1901 these deaths used to number 30 and more in a twelvemonth.

### CANCER RESEARCH IN MANCHESTER.

In Manchester, last summer, Dr. R. Veitch Clark, the medical officer of health, invited a number of medical practitioners and others interested in cancer research to form a committee, and several meetings have been held. This committee is now being enlarged by the addition of representatives of all the hospitals, the University, and other public bodies concerned; the Manchester Public Health Committee is co-operating actively. Certain lines of investigation have already been drawn up and proposals made to centralize the available funds; researches are being planned from geographical, industrial, and medical standpoints.

## SPECIAL SCHOOLS FOR DEFECTIVE CHILDREN.

The Board of Education has issued a circular<sup>1</sup> to local education authorities on the provision of special schools. There are in England and Wales some 150,000 defective children—blind, deaf, and physically and mentally defective; for these there are not more than 41,000 places in special schools. The obligation on local authorities to make this provision is of recent date (1914 and 1918); this, the war, and money difficulties account for the deficiency. The Board thinks that there is now no reason why the legislative provision should not be brought into being. It aims at the prompt ascertainment of all the children affected and for whom there is now no educational provision, and the speedy provision of proper facilities. From returns of defective children in the possession of the Board index figures for all areas will be provided, and should the returns of local areas be widely different from the index figure it is suggested there is ground for special inquiry. The Board prescribes no rigid order of priority in the types of schools needed; but it suggests that those for blind and deaf should come first, for the numbers concerned are comparatively small; then should follow a good orthopaedic scheme; next provision for the mentally defective; and, finally, open-air schools for the pre-tuberculous child. Provision for the mentally defective is the most difficult; but it is suggested that certain steps can be taken with little cost as a basis of a complete scheme—namely, a correct list of the children, notification of suitable cases under the Mental Deficiency Act, and supervision of children for whom no special schools exist.

## Ireland.

## MEDICAL REFEREES IN THE FREE STATE.

In connexion with the conditions of appointment of medical referees under the Insurance Act a meeting of the Cork borough medical practitioners expressed very strongly their dissatisfaction with the conditions of service, especially in the following respects: (1) the salary is altogether inadequate; (2) provision should have been made for a higher age limit than 45 years; (3) preferential treatment in making the appointments for medical men who had served in the Army Medical Service of the Free State was considered particularly objectionable, as during the recent troubles in Ireland the wounded were mainly treated by civil medical practitioners without remuneration. The Irish Medical Committee was informed during the week by the National Health Commission that the personnel of the Selection Board appointed by the Civil Service Commissioners to review applications for the positions of medical referees is as follows: Dr. Maguire, National Health Insurance Commissioner; Dr. C. Dickson, chief medical officer to the Civil Service Commission; and Colonel T. O'Higgins, Director of Army Medical Services. It appears that a recommendation by the Insurance Commission that the Irish Medical Committee should be invited to nominate two of its members to act on the Selection Board was turned down by the Civil Service Commission. It is now nine years since the British Government had agreed to appoint whole-time medical referees at much higher salaries, and that Government was also prepared to accept the proposal that representatives of the Irish Medical Committee should have a voice in the selection of the medical referees. The idea was that these medical referees, in the discharge of their duties, would be continually coming into touch in a consultant capacity with members of the profession generally, and that by giving the profession a voice in their selection it would be only approximating matters to the customs that work satisfactorily in private practice. In this respect and in the matter of increased remuneration the Insurance Commission was prepared to a considerable extent, in the circumstances, to meet the claims put forward by the representatives of the profession, and did actually in these respects make certain recommendations, which were turned down by the Civil Service Commission and the Department of Finance. There is a strong

and growing feeling amongst the profession in the Free State that several of the Government departments are acting towards it in a very unsympathetic manner. The rejection by the Civil Service Commission of the proposal of the Insurance Commission to include representatives of the Irish Medical Committee on the Selection Board for the recommendation of medical referees is considered offensive, even altogether apart from the constitution of the Free State in regard to vocational privileges. The salaries which are being directed by the Local Government Department to be paid in recent appointments in tuberculosis and mental hospitals are so low that the members of the local authorities protest against them, and point out that the remuneration offered is lower than that paid to the attendants and porters. It is believed at the moment that there is not a medical administrator in the Ministry of Local Government in receipt of £1,000 per annum including bonus. The salaries of medical inspectors are what they were fixed at almost fifty years ago—namely, an initial salary of £500 per annum, reaching after seven years a maximum of £700 per annum. There are only six medical inspectors in the Local Government Department engaged in inspection work under the Medical Charities Acts. These inspectors, to qualify for their appointments, should have spent seven years in practice and have a diploma in public health or sanitary science. To obtain a diploma in public health under the old regulations meant a six months' course and involved a cost of from £400 to £600 for practitioners, who had to leave their practices to study for it. This sum, added to £1,500—the amount estimated that it costs a man to get a registrable qualification to entitle him to practise medicine—means, in addition to other things, that to become a medical inspector in the Irish Local Government it will cost him for his professional attainments about £2,000. For this outlay, in addition to his numerous important duties with regard to public health and other work, the Free State Government thinks he is amply rewarded with a salary of from £500 to £700 with bonus. Nevertheless, the same Government pays a trade inspector £1,000 and bonus per annum, and head clerks each receive £700 to £850 with bonus. The cost of the education and the training of each of these officials need not have exceeded £25 altogether.

## Scotland.

## PROFESSOR MATTHEW HAY.

PROFESSOR MATTHEW HAY, M.D., LL.D., was presented with his portrait in oils, by Mr. Charles Sims, R.A., at a meeting in the Aberdeen Art Gallery on January 14th. The portrait represents Professor Hay seated in academic robes. The frame of the picture bears the inscription "Matthew Hay, M.D., LL.D., Professor of Forensic Medicine from 1883, Medical Officer of Health for the City 1888-1923. A civic and academic tribute, 1925. Painted by Charles Sims, R.A." The ceremony, over which Sir George Adam Smith (Principal of Aberdeen University) presided, was attended by a large company of university and civic authorities. The presentation was made by Lord Provost Meff, who said that the city desired to be associated with the University in honouring one who had done so much to raise the two bodies to the high position they occupied to-day. Professor Hay had come to Aberdeen in 1883 to succeed Dr. Francis Ogston in the chair. From 1888 onward he had been medical officer of health for the city and had raised its health department to a level which had made it a model of method and efficiency, and had given it an enviable status among municipalities. One of the first tasks undertaken by Professor Hay when appointed M.O.H. was the re-organization of the City Hospital. He had known how to win public confidence for the institution; it was to-day one of the most modern of its kind in the country. The portrait now presented, after being exhibited in the Art Gallery for a short time, would find a permanent place within the University. He also presented to Professor Hay a replica for his own keeping. The Principal, in accepting the portrait for the University, paid a warm tribute to Professor Hay's great services to it. He had been loyal to all

<sup>1</sup> Circular 1249, January 12th, 1925, Board of Education, London, S.W.

the faculties, had never spared himself, and had been an example of unselfishness, devotion, and courage to all who worked with him. In particular he had rendered great services to the financial department, and it was due to him that the finances were in a very healthy condition. The University would pass the portrait on as the monument of a man who had adorned the University by scientific eminence and had contributed more largely than any man of his generation to its usefulness and efficiency. Professor Hay, in returning thanks, said the honour done to him was greatly enhanced by the fact that both town and gown had shared in its bestowal. He said that universities, like other social and educational services, had profited greatly in recent years by the much more liberal view taken by the Government of its obligations towards the support of higher education, although much was still being left to private benefaction. There therefore remained great opportunity for private benefactions, especially for the provision and extension of buildings and for the elevation to chairs of some of the now very numerous lectureships. It was gratifying to observe how greatly laboratory research had grown in the universities within the last forty or fifty years, and a university should cultivate and encourage the spirit of research both within and without its walls. Before the end of the ceremony the Principal presented a silver tea service to Mrs. Matthew Hay.

#### SIR HAROLD STILES.

The resignation of Sir Harold J. Stiles, Professor of Clinical Surgery in the University of Edinburgh, has been tendered to the Secretary for Scotland and accepted. The resignation will take effect at the end of the present term in March, and at the same time as he relinquishes his chair in the University Sir Harold Stiles intends to retire from private practice. It is understood that he has been induced to give up his professional and University duties nearly three years before reaching the retiring age limit on account of feeling that the strain of so much operative work, teaching, examining, and administrative business connected with the University is proving too exacting, and no one can deny that he is right to take things easy while still in good health and capable of enjoying life. Sir Harold Stiles has had a strenuous and successful career, and has proved a popular and acceptable university teacher, being the fortunate possessor of an extremely lucid power of exposition. His orthopaedic work at Bangour Hospital during the war was specially valued by his professional colleagues, and earned for him the honour of knighthood. In 1886 his original work in cancer research secured for him the award of the Walker prize given quinquennially by the Royal College of Surgeons of England, and the prominent part that he took in drawing the attention of the public and of medical men to the importance of milk in relation to tuberculosis is well known. He was appointed Clinical Professor of Surgery to Edinburgh University in July, 1919, and he is at the present time President of the Royal College of Surgeons of Edinburgh and has been President of the Association of Surgeons of Great Britain and Ireland.

#### PROSPECTIVE ANNEXES TO EDINBURGH ROYAL INFIRMARY.

At a meeting of the Edinburgh Merchant Company held on January 15th, the Master, Mr. M. A. T. Thomson, presiding, a report was presented by Mr. Henry Darling, LL.D., representative of the company on the board of managers of the Royal Infirmary. It referred to various matters, such as the development of the ear and throat department, the new radiological department, and the Rockefeller laboratory, which have been fully described in recent issues of the *BRITISH MEDICAL JOURNAL*. In these various additions and extensions an outlay of £104,000 was involved, and the managers already had or knew where they could get the money. The managers, however, had now on hand a more extensive scheme which intimately concerned the Merchant Company in the acquisition of the site, buildings, and surrounding ground of George Watson's College. Among other purposes this space would be utilized by the infirmary for more adequate residential quarters for the nursing staff, and also for a new and up-to-date maternity hospital. For the latter purpose an

appeal to the public for £250,000 would eventually be made jointly by the Royal Infirmary and the Maternity Hospital. The present maternity hospital would be converted into a maternity and child welfare centre. Closely associated with the infirmary, and in its immediate proximity, there would also be erected the contemplated but hitherto deferred Lister Institute for research, and there would also be an institution for the care and cure of cancer, as provided for under the Melville trust.

#### THE FUTURE OF SURGICAL TEACHING IN EDINBURGH.

Professor D. P. D. Wilkie, M.D., Ch.M., who was appointed to the chair of surgery in Edinburgh University last summer, delivered an inaugural address on the future of surgical teaching in Edinburgh in the Melville Hall on January 13th. Principal Sir Alfred Ewing, who presided, said that the chair of surgery would be occupied in future as nearly as possible on a whole-time basis. Professor Wilkie at the outset of his address paid a tribute to Professor Caird and Sir Harold Stiles, to whose teaching he had owed much, and referred to the distinction of his predecessors in the chair, the late Professor Alexis Thomson, and Mr. Alexander Miles who had acted as interim professor. He believed that there were three main functions of a school of surgery. In the first place it must provide teaching for the undergraduate in the science of surgery and must train him in the application of the science to human suffering; secondly, it must provide more advanced training for those who meant to devote themselves specially to surgery; and thirdly, the energy of a surgical school must rest to a large extent on the spirit of research and inquiry which pervaded its departments, stimulated its teachers, and fired the imagination of its students. Lectures should not be a condensed substitute for the textbook. It should be the endeavour of teachers to crystallize their knowledge on the principles of their subject. Students should persistently demand proofs of all they were taught, and it would be his endeavour to teach largely by demonstration. There was a necessity for junior posts on the hospital staffs with sufficient emolument not to deter anyone with brains from a practical training in surgery. As to post-graduate teaching, it was surely possible, by co-operation and adjustment, to provide some organized scheme of clinical instruction. Speaking of experiments on animals, Professor Wilkie referred to the necessity for constant practice in inquiry, and held that only by control experiments on the lower animals could we hope to gain that accurate information upon which all science must be based. Nobody could tell where the next great advance in surgery would come, and the field for research was constantly widening. The surgery of the heart, for example, was no longer confined to occasional dramatic attempts to remove a bullet or stitch a stab wound; but experience had demonstrated that there was a possibility of direct surgical interference in cases of valvular disease of the heart, and further research was necessary to bring that discovery within the bounds of safe surgical practice. In regard to cancer, any new idea that might help in solving that problem must be fostered and encouraged. The future of surgery in Edinburgh would depend on the research work of the younger surgeons and this should be endowed so that younger men would be free from financial cares. It had been said that the discoveries of Pasteur saved enough money to pay the French indemnity in the Franco-Prussian war, and in the same way it could be said that in the saving of life and limb the work of Lister had meant in this country alone double the cost of the great war.

#### ROYAL COLLEGE OF PHYSICIANS ANNUAL DINNER.

The annual dinner of the Royal College of Physicians of Edinburgh was held on January 16th in the hall of the College, when Professor G. Lovell Gulland, C.M.G., President, was in the chair. After the loyal toasts, "The Imperial Forces" was proposed by the Vice-President (Dr. J. Craufurd Dnlop) and acknowledged by Rear-Admiral Sir Reginald Tyrwhitt, Commanding Officer, Coast of Scotland; "Our guests" was proposed by Professor G. M. Robertson and acknowledged by the Right Hon. Sir John

Gilmour, Secretary for Scotland; "The Scottish Universities" was proposed by Dr. Claude B. Ker and acknowledged by the Right Hon. Sir Henry Craik; and finally, "The Royal College of Physicians and its President" was submitted by the Marquess of Linlithgow and acknowledged by the President.

#### PREVENTION OF INFECTIVE JAUNDICE.

The regulations of the Scottish Board of Health for dealing with spirochaetosis icterohaemorrhagica are to continue in force until the end of 1925. The disease is to be notified by practitioners or attendants to the local officer of health, a fee of half a crown being paid for each notification. The Board has made arrangements for the examination of specimens in the pathological laboratory at the Royal Infirmary of Edinburgh.

#### NEEDS OF SCOTTISH HOSPITALS.

(Continued from page 138.)

The Hospital Services (Scotland) Committee appointed by the Scottish Board of Health to inquire into the inadequacy of hospital services in Scotland resumed its sittings on January 13th, under the chairmanship of the Hon. Lord Macenzie. General practitioners from various districts and members of the staffs of district hospitals were examined last week.

Dr. Cromie (Castle Douglas) emphasized the growing necessity in medical cases for other and better forms of treatment than bottles of medicine. He said that in the counties of Kirkcudbright and Wigton there were 31 beds in general hospitals for a population of over 60,000. It was true that most of the surgical work was done in Dumfries, Ayr, Glasgow, and Edinburgh, but the hospitals in these centres were admittedly overcrowded, and the early treatment of cases difficult. Factors which would tend to diminish the demand for hospital treatment were improved housing and an improved system of home nursing. He believed it would be a mistake to support hospitals from the rates, as this would destroy the voluntary principle.

Dr. G. R. Livingston (Dumfries) said that there was a shortage of hospital accommodation in the three south-western counties, and that there had been an enormous increase in the work done in the Dumfries Hospital during the last twenty years, so that the accommodation did not now meet the demand. To take paying patients would require a new hospital, and it was felt that the accommodation that convalescent wards would be a great advantage. He stated further to payment by patients if the accommodation could be provided.

Dr. P. F. McFarlan (Stirling) said that in Stirling Royal Infirmary the present accommodation was insufficient for the demand, and further provision was necessary, particularly for medical cases. The work in the Infirmary was increasing and would undoubtedly increase more rapidly with a larger and more fully equipped institution, and he did not think that increased housing or home nursing facilities would decrease the demand for hospital treatment. He thought that in a country town it was inadvisable that the public health authority should provide separate hospitals for general illnesses, but he thought that, if there was full co-operation between the public health authorities and the voluntary hospitals, the latter had a right to expect financial help both from the State and from the local rates.

Dr. A. E. Hunter (Falkirk) said that the present accommodation in Falkirk Infirmary was inadequate, especially in the surgical department. So far as this infirmary was concerned, he thought that either a new hospital or extension of the present one was preferable to auxiliary hospitals. In this district housing was impracticable from the home nursing point of view, he thought treatment was the only remedy. He thought that there should be more accommodation in existing hospitals, both for medical and maternity cases, and even better housing conditions would not help this problem.

Dr. Alexander Trotter (Perth) said that hospital accommodation in this area was inadequate, the average waiting list being 30 for 150 beds at the Royal Infirmary, and there was need that further provision should be made for convalescent and for chronic and incurable cases. This infirmary received paying patients, who were accommodated in private wards off the large wards, and the demand for this was likely to increase in the future. He thought that better housing and better home nursing would reduce the greater amount of illness, but the relief to the hospitals would be pressure on the medical side than on the surgical side, where the functions of the Poor Law should be abolished. The outdoor cases should be treated through the National Insurance Act, and the Poor Law hospitals should be taken over by the local authorities. He was in favour of the continuation of the voluntary principle, and saw no objection to hospitals receiving paying patients.

On January 14th the Committee examined witnesses from the Highland area.

Dr. J. B. Simpson (Golspie), speaking for the county of Sutherland, said that hospital accommodation for surgical cases was fairly

adequate. With regard to medical cases, he was not so sure, but on the whole he might say that the present provision met the present demand. Any additional provision that might be required should be made by the extension of existing hospitals. He thought that medical practitioners in the country could render large assistance in reducing their waiting lists if the selection of cases for these hospitals was carried out with due care and appreciation of the treatment required by the patients. From a financial standpoint also he believed that the contributions from the northern Infirmary were totally inadequate in proportion to the number of cases treated in the south.

Dr. K. Campbell (Oban) contended that the present provision for treatment of illness in his area was inadequate, particularly with regard to accommodation for chronic and maternity cases. Operations were carried out by the operating surgeon, who visited the hospital once a month. Dr. Alexander Asher (Thurso) said that in the county of Caithness, with a population of about 28,000, there were two hospitals, which he did not consider met the present demand with regard to equipment, although he considered that the available buildings might be made to do so. He thought that the deficiency chiefly extended to surgical and maternity cases.

Dr. T. F. Dewar, Medical Officer of the Scottish Board of Health, was examined with regard to the hospital facilities for the sick poor in Scotland. He said that poorhouses had been built all over Scotland, the total number being between sixty and sixty-five, and from time to time the accommodation set apart for the sick in these poorhouses had been improved or extended. In a few cases buildings of entirely modern type had been recently erected, but for the most part, the accommodation provided for the sick in the same as it was in the middle of last century. He thought that there would be great, if not insuperable, difficulty, both structural and administrative, in the way of utilizing this accommodation for the general sick of a locality without relation to the legislation regarding the poor in Scotland took place, the structural difficulty would remain, and it was not easy to see how general hospital provision of the country. In a number of instances, however, such as the poorhouse hospital blocks at Paisley, Govan, Craiglockhart, and Dundee East poorhouses, the arrangement of the buildings was such that the structural separation which already existed might be followed by complete administrative separation. With regard to these Poor Law hospitals, probably they were in all essential respects admirable and were ready for conversion to general hospital purposes. He did not think that at the present time in the eastern section of Scotland there were beds in Poor Law hospitals which could be utilized for general hospital purposes with advantage.

The Committee continued its sitting on January 15th, when five witnesses were examined.

Dr. G. Dick (Wick), giving evidence from the public health point of view, stated that housing was an important factor in crofting counties. In the burgh of Wick, where a maternity and child welfare scheme had been in operation for four years, the health visitor reported that in about 20 per cent. of cases of notified illness the home conditions were not suitable. Home nursing facilities were, therefore, not likely to modify the demand for hospital accommodation. This witness proposed a central hospital for the northern counties fully equipped for special diagnosis, treatment, and investigation, with local cottage hospitals as clearing stations, and he thought that State grants and assistance from local authorities would be necessary. He also approved of the suggestion that a hospital ship should be brought into use for the outer islands and Orkney, particularly to serve the fishing population and places which were inaccessible by land, such as in the north-west of Sutherland.

Dr. J. Pender Smith (Dingwall) said that the number of hospital beds in his area was fairly adequate. He suggested that in remote districts, for purposes of operation, conditions might be improved by establishing a district nurse's house, with operating room attached.

Dr. A. L. Tuke (Dunfermline) said that the Dunfermline Hospital had already been extended three times, and was overcrowded still, the present provision not even approaching the demand. There was no accommodation, unfortunately, for people able to pay a moderate fee, and such accommodation would supply a greatly felt want.

With regard to maternity cases, there was a maternity home at Dunfermline where 162 cases were dealt with last year, but this did not suffice for the needs of the situation. He thought that insurance companies might give ample contributions, these contributions largely depending upon how much these societies utilized the hospitals, but he did not approve of maintaining special hospitals for insured persons, as this would immediately bring about a class distinction, which would be a bad thing. Nor did he approve of local rates for hospital purposes, which would interfere with voluntary effort and independent management. He saw no insuperable objection to co-operation with regard to Poor Law patients. At Dunfermline the existing Poor Law hospital had been used as a V.A.D. hospital during the war, and would make an excellent medical hospital where other activities such as maternity, child welfare, etc., could be carried out. He estimated that for the medical needs of the district 120 beds were necessary.

Dr. J. Mackenzie (Inverness) said that the hospital buildings there were opened in 1804 and were out of date, but there was ample ground for extension. About sixty beds were required, as well as new equipment. The greatest need in this area was for surgical beds, and there was also need for providing treatment for venereal disease and for maternity cases. An increasing demand for some kind of provision for paying patients was also being

experienced. He thought that by voluntary subscription enough could be raised to maintain the extended hospital.

Dr. J. Laurie (Greenock) said that the accommodation in Greenock Infirmary was inadequate, especially as regarded the admission of female cases. There were two separate wards for paying cases, and this provision worked admirably. This witness was in favour of voluntary management and of the sick poor being taken out of the realm of the Poor Law.

The Committee adjourned until January 20th, and will take evidence from the representatives of the boards of management of several general voluntary hospitals.

## Correspondence.

### TREATMENT OF PERFORATED GASTRIC AND DUODENAL ULCERS.

SIR,—I agree with Mr. Zachary Cope that a short-circuiting operation should not be accepted as a routine procedure for the treatment of perforated gastric and duodenal ulcers. At the same time in my experience those patients in whom it has been performed successfully have definitely a more uneventful and straightforward convalescence than those in whom the perforation only has been closed.

It is well to bear in mind that the operation for a perforated ulcer is essentially a life-saving operation when a particular catastrophe has to be dealt with and does not necessarily call for curative measures for the cause itself. In those patients, though, who are operated on early and the general condition easily permits of it, in my opinion a gastro-enterostomy should be performed when the ulcer is situated in the pyloric region; but if there is the least doubt in the surgeon's or anaesthetist's mind that the extra time and manipulation may produce a risk it is far better to do the least possible. It is surprising how seldom a complete mechanical obstruction is produced by the actual closure of a perforation, though of course it does occasionally occur.

During the summer months of last year I operated on nine cases of perforated duodenal ulcer at the Willesden General Hospital (seven were admitted direct from the Empire Exhibition at Wembley), with one death in a man of 58 who was almost in *extremis* before operation. The others, seven men and one woman, all between 30 and 40 years of age, were operated on at intervals after the perforation varying from four to eight hours, and in each case when the perforation had been closed posterior gastro-enterostomy was performed. With one exception they were discharged from hospital within four weeks of the operation in good condition; the exception was a man who had been badly gassed in the war and developed severe post-operative bronchitis; he burst open his wound, but eventually recovered.

From these and previous cases my impression is that if the operation is done within eight hours of the perforation, in the majority of cases gastro-enterostomy may safely be performed, but that after this interval the risk is greatly increased, since the peritoneum about this time becomes definitely infected, with consequent absorption and paresis of the gut.—I am, etc.,

London, W., Jan. 16th.

F. D. SANER.

SIR,—I feel that Mr. Zachary Cope, in his letter published in your issue of January 17th (p. 139), has not quite understood the purport of my paper. The routine treatment in the past of perforated gastric and duodenal ulcer has been suture and drainage only, involving the possible need for a gastro-jejunostomy later. I wished to show (1) that in skilled hands it was possible for an immediate gastro-jejunostomy to be performed in about 50 per cent. of all cases without increasing the gross mortality of the series, and (2) that by so doing the ultimate results were improved. The prime duty of the surgeon in operating on a grave abdominal emergency, such as a perforated ulcer, is to save the patient's life, and if he feels that to perform a gastro-jejunostomy is to add materially to the operative risk he should not do it. My own experience was to perform the operation in seventeen cases before I lost one, and this was an exceptional and rather misleading case.

The series quoted by Mr. Cope, with a gross mortality

about the same as my own, includes sixteen cases of immediate gastro-jejunostomy with three deaths. I will freely admit that, had my own experience been so unfortunate, I should have felt that I was taking unjustifiable risks, and, like Mr. Cope, I should have performed the complete operation much less frequently. But, after all, a surgeon must be guided by his own results, not other people's, and the problem is really that of a careful selection of cases.

With Dr. Tonking's letter I entirely agree, and I should like to congratulate him on his excellent results.—I am, etc.,

Birmingham, Jan. 15th.

G. PERCIVAL MILLS.

### POSTURE AND REST IN MUSCULAR WORK.

SIR,—In a review of Report No. 29 of the Industrial Fatigue Research Board on the effects of posture and rest in muscular work (p. 130 of the JOURNAL) you state that the papers contained in the report have a practical interest, not only for employers, but for manual workers. At the same time you doubt whether the latter would take the trouble to understand the reports, and you point out further that the reports of the Board in general "rarely make any attempt to be interesting, although the subjects with which they deal are often such as closely concern everyday life; there is seldom, if ever, any promise that the information they contain will be translated into practical benefit." You then suggest that the editors of such reports should describe, in an interesting way, why the investigations were undertaken and the benefits which the new knowledge offers.

I am writing to point out that your suggestions are already carried out to a large extent in the annual reports of the Board, which summarize in general terms the detailed information embodied in the individual reports. In addition, the reports usually include articles on various topics of current interest, written by the senior investigators, though I cannot guarantee that they, or the summaries mentioned, attain the degree of lucidity and interest which you demand. With regard to your doubt whether the information contained in the reports of the Board is ever translated into practical benefit, may I refer you to the *Journal of the National Institute of Industrial Psychology*, where you will find several articles describing the application of results obtained by the Board's investigators to actual practice in factories—for example, the utilization of certain methods of motion study in the packing of chocolates, and the hewing of coal in coal mines?

At the same time, it must be admitted that the average British employer is very slow to avail himself of the information adduced by the Board's investigators. The British race, taken as a whole, is a very conservative one, and will not be hurried in adopting fresh ideas; but we are confident that it is only a question of time before the usefulness of our work will receive more practical recognition. The collaboration of the National Institute of Industrial Psychology with the Fatigue Board will hasten this process considerably, for the investigators of the Institute, who are usually engaged in carrying out inquiries of immediate practical utility at the request of various employers, are well acquainted with the Board's reports, and are always very ready to translate their information into practice.—I am, etc.,

Oxford, Jan. 17th.

H. M. VERNON,  
Investigator for the Industrial Fatigue  
Research Board.

### WET WINDS AND EARLY PHTHISIS.

SIR,—It is with diffidence and regret that I must continue to oppose Dr. Gordon's conclusions on this subject (November 29th, 1924, p. 983). If they were true, sufferers would benefit and our work be greatly simplified.

1. I do not wish to enter verbal side-tracks; if Dr. Gordon prefers "conclusion" to "hypothesis" we will adopt his choice. "Belief" might be an even better word.

2. The same remark applies to the word "axiom" in reference to sheltered areas; but we must then regard Dr. Gordon's statement as one of the *obiter dicta* of great men, for no evidence whatever is adduced, or quoted, in support. He writes:

"As regards shelter and exposure I have found in long practice that 100 feet of altitude shelters half a mile to the leeward of it well and a further half a mile fairly."

I have made no anemometric experiments to disprove this, but my work necessitates lunch in the open all the year round, and I am frequently driven to seek shelter from wind. Now there may be sheltered spots on the leeseide and in close contact with an ordinary hill, but most of these are due to some further modification of the land, and to say that 100 feet shelters well for half a mile is untrue. A 10-foot wall affords better shelter than a hill, but even then I would anchor as close as possible to its base, not 88 yards away, or even 5 feet, if nearer approach were possible.

3. *Malleable Statistics*.—Other observers (Drs. Adkins and Date), investigating independently Dr. Gordon's decisions about shelter or exposure, but with no knowledge of the patients' fate, differed from him in 58 per cent. of 113 cases. Dr. Gordon's remark about Torquay illustrates again the scope for difference of opinion; so perhaps the word "malleable" is justified.

4. *Mauvaise Plaisanterie*.—I must again confine myself to personal experience. At Dr. Gordon's suggestion Devon T.O.s prepared statistics of the results of treatment in early phthisis. He then wished to enter on a rather low scale map the result and position (sheltered, exposed, or undetermined). This seemed to me most unsatisfactory, and foreseeing, but hoping to avoid, the present controversy, I wished Dr. Gordon to enter my cases himself. He insisted, however, on my being present to assist, and drove over with the list to my hospital at Torquay. He then marked the map in my presence and there seemed to me no doubt that what I have named "sub-conscious moulding" took place. Dr. Gordon was inclined to make me co-responsible for the result, but I was unwilling. Had I agreed, or not actively disagreed, I should have been classed as an "able collaborator" and not, alas, merely a "mauvais plaisant."

Dr. Gordon writes wisely and well. In the paragraph on "approximate isolation of influences" and elsewhere, it appears as if every scientific precaution was being taken; but a careful reading of the paper does not confirm this, and before we commence to base practical measures on these conclusions further investigation, as suggested in my previous letter, is surely necessary.

Opinions differ widely as to the influence of climate and meteorology on disease. The subject merits careful investigation (perhaps it should be included in the collective work of the Joint Tuberculosis Council), and if Dr. Gordon stimulates others to undertake this his work will be well worth while.—I am, etc.,

Paignton, Jan. 10th.

E. WARD.

#### THE RURAL PRACTITIONER AND MATERNITY.

SIR,—I am tempted to break a long-established rule of abstinence from epistolatory discussion by noting in your issue of January 3rd (p. 41) a complete misstatement by Dr. Maurice Mottram of some remarks of mine made at the recent discussion at the Royal Society of Medicine on puerperal sepsis. I shall so far observe my rule as to abstain from any further discussion of the matter, merely quoting in parallel Dr. Mottram's account of what I said and the report published in the *Proceedings of the Royal Society of Medicine* for January, 1925.

Dr. Mottram.

Dr. Stevenson blames the doctor and absolves the midwife. This is a very serious charge and appears to be based solely on his interpretation of certain figures.

*Proceedings.*

It would be a point of general utility to know in whose practice these deaths occurred, whether it was in the practice of doctors or of midwives; it could be easily determined by a tabulation of available records. About four years ago he noticed that at that time, when the proportion of cases attended by midwives could be held to have declined, owing to the return of practitioners from military service to their civilian duties, there was a sudden and very appreciable rise in the mortality from puerperal fever. He would be content with merely stating the fact, and suggesting that it constituted a further reason for making the tabulation he urged.

The quotation from the *Proceedings* shows that I carefully refrained from any attempt at apportionment of the responsibility for the present state of affairs. If Dr. Mottram regards the mere statement, without comment, of

a definite fact, open to anyone to verify for himself, as blame of the doctor and absolution of the midwife, I can only surmise that he feels the facts of the case to be against him. I am by no means sure that they are, and should like to see the question settled by obtaining the record suggested.—I am, etc.,

London, W.C.2, Jan. 14th.

T. H. C. STEVENSON.

#### NOTIFICATION OF PUERPERAL SEPSIS.

SIR,—The discussion on the "Notification of puerperal sepsis," at the Royal Society of Medicine, published in this month's *Proceedings*, brings out two points: (1) a difficulty in defining puerperal sepsis; (2) evidence of a disinclination on the part of doctors to notify such cases early, and sometimes not until a fatal termination ensues. As to the nomenclature, I would suggest, as was done by the late Herbert Williamson, "puerperal fever" or "pyrexia" as implying nothing more than fever during the puerperal period, and I would make notifiable a temperature over 100° F. persisting for twenty-four hours. It should be a rule that a temperature chart should be kept with morning and evening record for six days, and once a day after until the tenth day. At the end of ten days it should be the statutory duty of the doctor or midwife to post the chart to the medical officer of health in every case, just as notification of birth has to be sent to him within thirty-six hours. The M.O.H. would thus have an enormous amount of statistical information at hand and evidence of any pyrexia. The knowledge that this record would reach the M.O.H. eventually would be an incentive to the doctor or midwife to notify pyrexia cases early, for if they had not done so an inquiry from the M.O.H. when the chart of such a case came to hand would at once show up the delinquent.

Early notification means early treatment and hope of recovery; late notification and postponed treatment, too often death. Co-operation between the doctor and M.O.H. should follow notification, and assistance in the form of nurses and food and specialist's advice, when wanted, would be forthcoming. Removal of such cases should be a matter of agreement between the patient, doctor, and M.O.H. Ample accommodation would be found for such cases in the general or special hospitals up and down the country. Maternal mortality demands that these cases should be notified, and I am convinced that by insisting on temperature records being sent in, in both normal and abnormal cases, early notification will follow with its good results, and will eventually be welcomed both by the patient and doctor or midwife.—I am, etc.,

Ipswich, Jan. 12th.

JOHN GUTCH, M.D.

#### FREUDIAN DOCTRINE.

SIR,—It is with unalloyed pleasure that I read Dr. Ernest Jones's letter in your issue of January 10th (p. 93) approving of Sir Bryan Donkin's proposal for a discussion of the above, and trust that it will be brought about.

Dr. Jones charges Sir Bryan Donkin with being misinformed about past discussions, and refers to various records. It appears to me that Dr. Jones does not answer Sir Bryan Donkin. Sir Bryan Donkin means discussion of the fundamentals, the foundations of the psycho-analytic doctrines, whilst Dr. Jones refers to discussions on psycho-analytic papers which take the foundations for granted.

Dr. Jones speaks of the Medical Section of the Psychological Society as the "most appropriate body of all" for such discussions! This is almost as bad as if we left an inquiry into the price of coal to the coal merchants! The Medical Section of the British Psychological Society is ruled, if not dominated, by psycho-analysts. There could not, in my humble opinion, be a less appropriate body for an impartial inquiry.

When my book, *A Critical Examination of Psycho-analysis*, appeared at the end of 1923 an eminent psycho-therapist, head of a well known hospital for functional nervous disorders, who had congratulated me on my exposure of the Freudian fallacy, approached the Medical Section of the British Psychological Society with the view of discussing the question. After consultation in committee, I am informed, such discussion was declined.

Whilst it is quite true, as Dr. Jones points out, that a critical notice by J. C. Flügel of more than eight pages was published in the *British Journal of Medical Psychology*, he omits to state that a rejoinder by me, refuting every point of Flügel's criticism, was declined by the editor, again after consulting his colleagues. My rejoinder received ultimately the hospitality of the *Journal of Mental Science*.—I am, etc.,

Shortlands, Kent, Jan. 14th.

A. WOULGEMUTH.

### WOMEN DOCTORS.

SIR,—It is encouraging to those interested in medical education to be informed by Dr. Robinson (January 17th, p. 149) of the efforts made by the more recently qualified women to gain special hospital experience in the diseases of children.

It is to be regretted, however, that their opportunities of obtaining resident appointments are still limited. Some of the medical schools enumerated, while giving equal opportunities to men and women as far as graduation, do not realize their further responsibilities, and have made no effort to throw open to their women graduates the resident posts in their own hospitals. This is manifestly unfair, and when choosing a medical school for their daughters parents should make careful inquiries respecting post-graduate opportunities.

Whether the woman graduate chooses a career in general practice, in maternity and child welfare, or missionary work, either abroad or in the slums of our great cities, a resident hospital appointment is invaluable, and to those desiring to specialize indispensable.—I am, etc.,

FRANCES IVENS,

President of the Federation of  
Medical Women.

Liverpool, Jan. 19th.

SIR,—I am sure that medical women will be grateful to Mr. W. Robinson for his letter in giving some figures—that is, 78 women doctors as applicants for a junior post at the Children's Hospital, Sunderland. His letter draws attention to such a serious state of affairs that the widest publication is necessary in order to secure a remedy. I refer to the fact that, owing to the few hospital posts (junior, senior, or honorary) now open to well qualified medical women, it naturally follows that when one post is available there will be a greater number of women candidates than a similar post when male applicants are required.

I think one may safely say that ninety-nine out of a hundred posts as house-physicians and house-surgeons are regarded as the strict preserve of the young male doctors, owing to the policy pursued and fostered so carefully by the selection committees of voluntary hospitals up and down the land to exclude all women doctors.

During the war there was a greater influx of both sexes of medical students to supply the needs of the nation, and the maximum was reached in 1919. In 1924 there came out a maximum of qualified men and women doctors from the medical schools.

But even with this increase the proportion of the newly qualified is about one woman doctor to five men. The total number of registered medical women is somewhere about 2,000 in Great Britain and the medical men registered are about 25,000. It is also true that the numbers of medical students (men and women) entering the schools are returning to the pre-war level. What is really needed is fair treatment for women from the selection committees so that there is an increase in proportion of all hospital posts that are open to women. I do not ask for hospital posts for all women in the same way, as equally qualified men do not get hospital posts.

While on this question, why is it that there are so few hospitals who have appointed women doctors in charge of beds on to the honorary staffs, yet the numbers of women and children to men patients to be treated are as 3 to 1 of all patients? Pure prejudice on the part of the male colleague, I fear, must be the answer. Public opinion has always been on the side of the woman doctor. Hence she must be allowed the same facilities to equip herself as her male colleague.

With the changes that must necessarily come over hospital management and finance, the methods of appointment must also change. I am sure the day will come when the hospital

patient will have the right of access to the services of a woman doctor. Every hospital which relies on an appeal to the public for support will have to see that a proportion of the honorary staff are women.

I am, of course, quite aware that the letter of Mr. W. Robinson is meant as a deterrent and warning to parents and intending medical women candidates as threatening future unemployment. Let me tell them to take no heed of such "Partingtons," for the public needs, and demands, medical women in many and ever-widening spheres. Our movement has too strong a hold to be pushed back, much as the reactionary would like it.—I am, etc.,

MAUEL L. RAMSAY, M.D.,  
F.R.C.S. Edin.

Plymouth, Jan. 12th.

### THE ELECTRONIC REACTIONS OF ABRAMS.

SIR,—I can only speak for myself, but I imagine that a number of other Fellows of the Medical and Electro-Therapeutical Sections of the Royal Society of Medicine would agree with me that the Communication of Sir Thomas Horder of January 16th must certainly rank as one of the most extraordinary and tantalizing communications that has ever been presented before a scientific society. As there was no time left for discussion, and discussion at a later date was not at present desired by those at the meeting, I can only hope that you, Sir, will allow a few comments through the columns of the *JOURNAL*.

Sir Thomas Horder disclaimed responsibility for the report except for a fifth share. But while, on the one hand, he emphatically declared for the final deposition as false gods of the oracular Abrams's boxes, his acute diagnostic instinct might have warned him that the effect on the lay public and on "electronists" of the encouraging gesture he made on the other hand in disclosing the 100 per cent. accuracy of certain incompletely described physical tests with Dr. Boyd's modifications, would only be to confirm in the minds of many of the public the rightness of their view that there still "may be something" in the original Abrams's boxes: and so, indeed, the *Morning Post* to-day (Saturday) interprets his committee's report.

One can only wish publication of any report had been delayed till further detailed announcements could be made with regard to the possible scientific or medical uses or not of Dr. Boyd's apparatus, or else that at least more information had been given as to the nature of the tests and responses in Dr. Boyd's almost magical copper-gauze lined cabinet. A 100 per cent. accuracy is almost too good to be true in most scientific work: it suggests that some simple solution for the cause of the phenomena must be there, to be found if only we can trace it. I shall only suggest briefly a few matters as to which I should have liked to have had information vouchsafed before a scientific meeting.

1. The nature and origin of the substances used in the tests. What was used besides "sulphur"? What proof, for example, was there that there was no radium present in the "active" substance? In more detail we should have heard how the "substances" were presented to the recording complex of apparatus and boys.

2. What the copper-gauze screen was supposed to shield the apparatus from: Were any experiments made to test whether, for example, wireless waves were reduced in amplitude in the cabinet, or neighbouring potentials of electric fields, such as those in the electric lighting circuits, were diminished or abolished? In short, what were the physical differences between the outer room and the inside of the screened cabinet?

3. Scientific experiments and results (with the rarest possible exception) can be duplicated at other times and in other places. Would Dr. Boyd be willing to submit his work to a London committee in London? The copper-gauze can be duplicated; are the Glasgow boys essential?

4. What interpretation does Sir Thomas Horder give for the epigastric percussion sign? He acted as what may be called the medical referee of the committee, and some attempt at explanation might have been expected from him at a medical gathering, of his findings on the boy, and his personal sensations when acting as indicator. The epigastric note on percussion depends obviously on two factors: (1) the contents of the stomach, transverse colon, etc., and (2) the thickness or rigidity of the abdominal wall. With

rigid rectus muscles the tympanitic note is masked, and the note is "duller." Now if the boy whose epigastrium is percussed has an abdominal wall contraction when the "active" substance is presented, he must have that (1) voluntarily, or (2) involuntarily, as a result of some sign or sensation—for example, when an electric current passed from his forehead electrode to the earthed plates on which he was standing. Now as currents as small as 10–12 ampère can be measured by Einthoven and Paschen galvanometers, and even smaller currents can be accurately estimated by almost infinitesimal differences of potential by quadrant electrometers and electroscopes (currents much smaller than those potential changes continually taking place at and near the epigastrium owing to the heart's contractions), it seems strange that physical measurements were not made, or at least were not given, of the probable current changes; also their differentiation from those detectable by the electrocardiograph. Indeed, with the refinements of scientific apparatus now available, it would seem difficult to realize what useful purpose the boy and his epigastrium can serve as an indicator! Is the boy as a "medium" or indicator more sensitive than a modern electrometer to potential differences? For Dr. Boyd's use of an "inductance" suggests that potential differences are at work in the production of his results.

In short, the whole position, from the point of view of those (especially of the Electro-Therapeutical Section, who were invited to the meeting, but were unable to express any opinions) who are more familiar with electrons and of electrical apparatus and measurements, was left most unsatisfactory, if not ridiculous. The whole matter seems to be as yet of no medical interest, yet medical developments were hinted at; so I can only suggest to Sir Thomas Horder and his committee that it might be well to allow a full and unbiased investigation to be conducted by a representative committee of, say, physicists such as Professors Sidney Russ and F. L. Hopwood, or physiologists who are familiar with physical experiments in medical subjects: then one may hope Dr. Boyd's vaunted advance on Abrams's methods will be removed from the atmosphere of thaumaturgy in which I for one felt the subject was left by the Communication to the meeting on Friday.—I am, etc.,

London, W.1, Jan. 17th.

J. H. DOUGLAS WEBSTER.

### THE NURSING DIFFICULTY IN THE SMALLER HOSPITALS.

SIR,—Dr. Nason's letter in your issue of December 27th, 1924 (p. 1214), very effectively expresses the fear that serious difficulty will shortly arise in obtaining probationers to be trained in the smaller hospitals now that the regulations of the General Nursing Council for qualifying for the *Nursing Register* have come into force.

His statement that "many of the most satisfactory nurses now employed throughout the country have been trained, and well trained, at these smaller hospitals" cannot be denied, and, indeed, it could hardly be otherwise.

I have for the past eighteen years been a member of the honorary surgical staff of a small hospital in one of the remote districts of England, ten miles from Land's End, and have consequently had some years of experience in the practical training of nurses suitable for small hospitals. In the hospital to which I refer the number of beds is nominally twenty-eight, but the average daily number of in-patients in hospital is forty-two. The total of in-patients for last year (1924) was 526, and the number of operations performed was 558, including 110 cases of appendicectomy (with three deaths), 10 of hysterectomy, 6 of hysterectomy (subtotal and total), 2 of gastro-enterostomy, 2 of prostatectomy, numerous laparotomies, 7 Caesarean sections, and 40 cases of tonsils and adenoids.

The nursing staff numbers twelve, including the matron, and the complete staff, including the matron, has been trained in the hospital. There is no house-surgeon. The nurses attend lectures delivered by the honorary medical staff, and are capable of passing the ordinary written examinations set to nurses in large hospitals.

The above figures speak for themselves in demonstrating the usefulness and certainty of the continuance in existence of the smaller hospitals, as also does the significant fact that both matron and nurses have all been

trained in the hospital, which shows how the small hospitals in remote districts have long since met and solved the problem of the nursing difficulty.

It cannot be denied that the surgical nursing experience in such a small hospital is, to say the least, considerable and varied, and medical experience is obtained by the cases of enteric fever and pneumonia which are admitted for treatment.

The individual responsibility and experience developed by a third year nurse in our small hospital is the outcome of her training in the wards (especially on night duty in charge of operation cases), in the casualty department, in the operating theatre, x-ray, and electrical departments. That she becomes a much more all-round, self-reliant, and valuable nurse than one trained in a large hospital has been the experience of the medical staff. In fact the nurse trained in a large hospital, with its environment of house-surgeons and students, has not, as a rule, the adaptability necessary to the requirements of the small hospital, and in many cases finds herself unwanted owing to her unsuitability. Affiliation arrangements with large hospitals have proved unworkable, and distasteful to the third year nurses who have tried them, owing to the fact that the large hospital usually treats them as newly entered probationers.

Dr. Nason's apprehensions as to the continuance of the supply of probationers of the right stamp for the small hospitals owing to the new regulations are not unfounded. But the certain demand of the small hospitals for probationers, their capability to train them for their own needs, and the certainty of the nurses when trained, although non-registrable, being able to earn their livelihood in, and in connexion with, the small hospitals, leaves no doubt that the supply of at least the present standard will continue.

The regulations of the General Nursing Council were probably aimed in their intention at putting a stop to the existing pernicious practice of allowing nursing homes to take untrained girls and send them out after a few months of so-called "training" in the nursing home to earn full nursing fees for the benefit of the home. One can hardly conceive that the General Nursing Council seriously contemplated penalizing the nurses trained in a small hospital.

It behoves the medical staffs of the small hospitals to unite with the nurses trained in them to bring pressure to bear on the General Nursing Council to reconstruct their regulations so as to recognize the claim to admission to the *Nursing Register* of the nurses trained in small hospitals, which is as undeniable as their efficiency is demonstrable. Surely the whole difficulty could be met by the General Nursing Council instituting a State examination for nurses, the passing of which would entitle the nurse to have her name placed on the *Nursing Register*, provided she had been trained in a bona-fide hospital, irrespective of the number of beds it contains.—I am, etc.,

E. C. EDWARDS.

Honorary Surgeon, West Cornwall  
Hospital, Penzance.

January 6th.

### HOSPITAL APPOINTMENTS.

SIR,—A relative of mine was recently a selected candidate for the post of house-surgeon at a hospital in a fashionable town on the south coast. The candidates were informed that the man appointed would be required to sign an agreement that he would not practise in the town for a period of five years under a penalty of £500. Needless to say, the advertisement of the vacancy did not mention this rather important proviso.

Several thoughts occur to me.

1. If the house-surgeon broke his agreement, who would take the £500?
2. Could the penalty be legally enforced?
3. Is such a proviso for the benefit of the honorary staff or the hospital?
4. Is the staff afraid of competition?
5. Does the committee think such a proviso improves its chance of obtaining the best house-surgeon?
6. Is this a modern innovation or a relic of the past?

Personally I cannot understand the lay members of the committee agreeing to such a handicap.—I am, etc.,

January 16th.

A HOSPITAL SURGEON.

## Obituary.

### CLEMENT DUKES, M.D., F.R.O.P., M.R.C.S.,

Consulting Physician to Rugby School.

We regret to announce that Dr. Clement Dukes died at his residence in Rugby on January 18th, at the age of 79. The son of the Rev. Clement Dukes, he was born in London in 1845, and became a student at St. Thomas's Hospital. He obtained the M.R.C.S. diploma in 1867; in 1869 he graduated M.B., B.S. Lond., with honours and a gold medal, and proceeded M.D. in 1876. After holding appointments at St. Thomas's Hospital, Great Ormond Street Hospital, the City Chest Hospital, and Moorfields Ophthalmic Hospital, he succeeded Dr. Farquharson as medical officer of Rugby School in 1871, and served under four head masters. When he retired from this post in 1908 he was appointed consulting physician to the school. During those thirty-seven years he acquired a world-wide reputation as a pioneer in promoting the health of public schoolboys, and as an authority on the hygiene of adolescence. His book *Health at School* is now in its fourth edition, and his *Essentials of School Diet* in its second edition. He also contributed articles on school health to *Morris's Book of Health*, and on the hygiene of youth to *Allbutt's System of Medicine*.

Dr. Dukes also won a well deserved reputation as a specialist in skin diseases. He contributed articles on scarlet fever and rubella to the *Encyclopaedia of Medicine*, and in 1900 he published in the *Lancet* an article entitled "On the confusion of two diseases under the name of rubella (rosé rash)." In this article he suggested that under the term "rubella" two etiologically and pathologically distinct infections were included. To the new disease thus brought to light he attached the title "the fourth disease," in consequence of its resemblance to scarlet fever, measles, and röteln. His conclusions attracted wide interest and were the subject of much discussion. He was awarded the Howard medal of the Royal Statistical Society in 1884; in 1911 he obtained the Bisset-Hawkins medal of the Royal College of Physicians, and he received the silver medal of the French Society of Hygiene. His other offices included those of justice of the peace for the county of Warwick, honorary consulting physician to the Hospital of St. Cross, medical referee to the Workmen's Compensation and Mental Deficiency Acts, and he had held the rank of surgeon colonel (V.D.) of the South Midland Brigade and the 2nd Volunteer Battalion of the Royal Warwickshire Regiment. He was chairman of the Northamptonshire Division of the British Medical Association in 1906, and president of the South Midland Branch in 1912.

Dr. NOEL STUART WHITTON died at his residence, Clyde Road, Fendalton, Christchurch, N.Z., on November 28th, 1924, after an illness of ten days' duration. He was born in Oamaru, N.Z., on December 9th, 1890. He was educated at Waitaki High School, and subsequently at Otago University, where he graduated M.B., Ch.B. in 1915. After spending a few months as house-surgeon at Hamilton Hospital he came to England, where he joined the R.A.M.C. In October of the same year he went to France as surgeon to the 9th Sussex Regiment. In France he was present at the battle of Loos and several subsequent engagements. He gained the Military Cross and was twice mentioned in dispatches. Subsequently he served in Mesopotamia and Palestine. He returned to New Zealand at the conclusion of peace, and joined the staff of the Christchurch Hospital as house-surgeon. A year later he again went to London for a post-graduate course; on his return to New Zealand he was appointed assistant surgeon to the Christchurch Hospital in the ear, nose, and throat department. In 1922 he married Miss Enid Taylor. He leaves a widow and one son. He was a member of the Canterbury Division of the British Medical Association.

We regret to record the sudden death, on January 10th, of Dr. PHILIP PREBBLE, a much respected Lancashire practitioner. He was a native of Blackburn, and studied medicine at the Universities of Aberdeen and Manchester. He

graduated M.B., C.M. Aberd. in 1895, and soon afterwards returned to Blackburn. He was physician to the Blackburn and East Lancashire Royal Infirmary and medical officer and public vaccinator for the third district of the Blackburn Union. Dr. Prebble had shown great interest in the work of the British Medical Association, which he joined immediately after graduation. He was a member of the Lancashire and Cheshire Branch Council for 1907-13 and from 1917 to 1923, the representative of the Division in the Representative Body for 1910-12 and again for 1919-23, and chairman of the Blackburn Division in 1914. He was also the representative of the town council on the Blackburn Insurance Committee. At the meeting of the Blackburn Insurance Committee on January 13th a vote of condolence with the relatives was passed. The funeral, which took place at Mellor on January 15th, was attended by many members of the profession and of representatives of the various bodies with which Dr. Prebble had been associated.

## Medico-Legal.

### REX v. BATEMAN.

An application for leave to appeal has been lodged in the case of Rex v. Bateman, one of the grounds being misdirection of the jury by the judge. The hearing will take place in a fortnight's time.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

At a congregation held on January 16th the following medical degrees were conferred:

M.D.—G. W. Theobald.  
M.Chir.—E. P. Brockman.  
M.B., B.Chir.—J. B. Leather, A. A. Lees, D. V. Snowman.  
M.B.—H. W. H. Holmes.  
B.Chir.—J. Gray.

\* Admitted by proxy.

### UNIVERSITY OF GLASGOW.

At the meeting of the Glasgow University Court on January 8th the Principal, Sir D. MacBrayne had off engineering, medicine is to be Scholarship in Med. tenable for three years also announced that Mr. MacBrayne had intimated his intention to give a donation of £1,250 to the Royal Infirmary for the endowment of a bed in the Infirmary in memory of his son, Lieutenant John Burns MacBrayne, 17th Highland Light Infantry, who was killed in the war.

### UNIVERSITY OF ST. ANDREWS.

A GRADUATION ceremonial was held at St. Andrews on January 16th, when the following degrees and diplomas were conferred:

M.D.—L. H. Henderson, J. Singh.  
Ch.M.—T. J. Mitchell.  
Ph.D. (Faculty of Medicine).—G. R. Ross.  
M.P.

D.P.H.—A. J. Campbell, G. G. Buchanan, W. M. Cumming, Olive M. Whyte.

## The Services.

### NAVAL MEDICAL COMPASSIONATE FUND.

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on January 20th, when Surgeon Vice-Admiral Joseph Chambers, C.B., C.M.G., Medical Director-General of the Navy, was in the chair, the sum of £60 was distributed among the several applicants.

### DEATHS IN THE SERVICES.

Lieut.-Colonel Louis William Swabey, R.A.M.C. (ret.), died at Bath on January 10th, aged 68. He was born in Canada, and was the son of the late Rev. Henry Birchfield Swabey. He was educated at St. George's, and took the M.R.C.S. in 1879 and the L.R.C.P. Ed. in 1880. He entered the army as surgeon on February 5th, 1881, became lieutenant-colonel after twenty years' service, and retired on February 5th, 1911. He served in the Egyptian war of 1882, receiving the medal and the Khedive's bronze star, and in the Sudan campaign of 1885, at Suakin, receiving a clasp. He also rejoined for service in the late war, from August 15th, 1914.

## Medical News.

A MOORFIELDS Research Scholarship, value £50 per annum, tenable for one year, but renewable for a further period of twelve months, has been initiated by the Medical Board of the Moorfields Eye Hospital, City Road, E.C.1, as a continuation of the Lang Clinical Research Scholarship at the hospital, which has now lapsed. Applications, and if possible suggested subjects for research, should be sent to the Honorary Secretary, Medical Board, at the hospital by January 31st.

WITH the view of encouraging original research in sanitary science the Grocers' Company offers scholarships, each of £300 a year, tenable for one year, but renewable for a second or third year. An allowance is also made to meet the cost of apparatus and other expenses in connexion with the work. Applications to be sent before April 1st to the Clerk of the Grocers' Company, Grocers' Hall, E.C.2, from whom forms of application and further particulars can be obtained.

THE Fellowship of Medicine announces that Sir Humphry Rolleston will deliver a lecture on the medical aspects of gall stones, on January 30th, at the Royal Society of Medicine, at 5.30 p.m. A combined course in diseases of children has been arranged by the Paddington Green Hospital, the Victoria Hospital, and the Children's Clinic, to begin on February 2nd. A four weeks' course, starting on February 2nd, will be held at St. John's Hospital for Diseases of the Skin. A comprehensive course at the London Lock Hospital will extend from February 2nd to 26th. Eight clinical demonstrations on tropical diseases will be given twice a week at the School of Tropical Medicine by Dr. Low and Dr. Manson-Bahr from February 3rd. The course in gynaecology at the Chelsea Hospital for Women, due to begin on February 2nd, has been postponed until March 16th. Copies of the syllabus of the above courses and the *Bulletin* of the Fellowship may be obtained on application to the secretary at No. 1, Wimpole Street, W.1.

THE North-East London Post-Graduate College is holding a special intensive post-graduate course from February 16th to 28th. The course will include demonstrations of clinical and laboratory methods used in the diagnosis or treatment of disease, and afternoon demonstrations of groups of selected cases, clinics in the wards and out-patient departments, and, at 4.30, a clinical lecture. The lecturers will be Mr. James Sherren, Dr. H. W. Barber, Dr. P. Manson-Bahr, Mr. H. D. Gillies, and members of the teaching staff. On the Saturday mornings there will be demonstrations on the early diagnosis of the infectious fevers, at the North-Eastern Fever Hospital, by Dr. F. Thomson, and on mental diseases, at the L.C.C. Mental Hospital, New Southgate, N., by Dr. S. J. Gillan. The fee for the course is 3 guineas, or 2 guineas for either week. Names should be sent to the Secretary of the Fellowship of Medicine (1, Wimpole Street, W.1), or to the Dean, Dr. A. J. Whiting (19a, Cavendish Square, W.1), by February 13th.

THE anniversary dinner of the Medical Society of London will be held at the Grand Hotel, Trafalgar Square, on Wednesday, March 11th, at 7.30 p.m.

A MEETING of the section of the Royal Microscopical Society formed to deal with the industrial applications of the microscope will be held at the house of the Society (20, Hanover Square, W.1) on Wednesday next at 7.30 p.m., when Professor R. Stenhouse Williams, M.B., will preside and deliver an introductory address on the fundamental importance of the microscope to the dairy industry. A series of communications bearing on the general subject will be made.

THE next meeting of the North-Western Tuberculosis Society will be held on Thursday, January 29th, at 3.15 p.m., at the Public Health Laboratory, York Place, Manchester, when Professor Topley will read a paper on infection and resistance in tuberculosis. Medical practitioners interested are invited to attend.

THE Red Cross Society of Russia announces that the third All-Russian Congress on Malaria will be held in Moscow, from February 3rd to 8th next. The questions to be considered include the transmission and epidemiology of malaria; the fight against malaria in Russia; and various scientific questions relating to malarial research. Inquiries should be addressed to the Sanitary Epidemiological Department, Narkomsdrav Moscow, Maly Teberkassky Perenkoi, Moscow.

MESSRS. OGILVY AND CO., scientific instrument makers, have removed their offices to 20, Mortimer Street, London, W.1, where special arrangements have been made for the demonstration of instruments.

THE income from all sources of the Metropolitan Hospital Saturday Fund for 1924 showed an increase of over £6,000 on the previous year's total of £100,765. The business house, workshop, and factory collection amounted to £79,583.

THE subject of the four lectures on physics to be given at Gresham College, Basinghall Street, London, E.C.2, by Sir Robert Armstrong-Jones during this term is the bodily senses and their mental representation. The lectures will be given on Tuesday, Wednesday, Thursday, and Friday next week at 6 p.m. on each day. Admission is free.

DR. J. WRIGHT HILL of North Woolwich, on the occasion of his retirement, has received from his friends and patients in the district a wireless set and other gifts in appreciation of his services during the past thirty-eight years.

THE Chapter-General of the Grand Priory of the Order of St. John of Jerusalem in England has authorized the publication of a summary of the more important activities of the Order in connexion with the Wembley Exhibition. An account is given of the investiture by the King in June, the annual general assembly, the annual commemoration service, and the conference of overseas representatives, which were held on the previous day. The publication is illustrated by photographs and an etching of St. John's Gate, Clerkenwell, by Mr. W. Monk; and includes a short article on first aid at the British Empire Exhibition, and a summary of an article dealing with the history of the Order, which appeared in the *Times* in connexion with these events. The publication can be obtained from the Chancery of the Order, St. John's Gate, Clerkenwell.

WE are asked to announce that the sixteenth international course of lectures on medicine will be held in Vienna, from February 9th to 21st, and will deal with the diseases of the digestive organs and their therapeutics. A special course of clinical work will follow from February 23rd to 28th. Inquiries should be addressed to the secretary, Dr. Kronfeld, Wien IX, Porzellangasse 22.

THE December issue of the *Revue d'Hygiène* is devoted to the proceedings of the eleventh Congress of Hygiene, held in Paris from October 21st to 24th, 1924, when papers were read by Dr. E. Dufestel on instruction in hygiene in elementary schools, by Dr. F. Humbert on the part played by the Red Cross in the teaching of hygiene in various countries, by Dr. Salmon on public health in England, by Dr. Montreuil-Strauss on instruction in sex hygiene, and by Dr. P. Kovindjy on the role of the doctor in physical education.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication.

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager, 429, Strand, London, W.C.2. Attention to this request will avoid delay. Communications with reference to editorial business should be addressed to the Editor, BRITISH MEDICAL JOURNAL, 429, Strand, W.C.2.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange). The telegraphic addresses are:

EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London.

MEDICAL SECRETARY, Mediscern Westrand, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

STRUCTURE AND COST OF A TEMPORARY WARD.

"W. A. M." writes: A cottage hospital is being built, but the scheme proposed cannot now be carried out owing to the lack of funds. The hospital consists of one floor only, and the addition of a children's ward would make the building complete. "W. A. M." asks for advice as to the best form of construction for a temporary ward for six beds, and a rough estimate of the cost.

TREATMENT OF TUBERCULOUS MESENTERIC GLANDS.

"P." asks for information as to the action of ultra-violet rays or injections of sodium morrhuate on tuberculous mesenteric glands.

## EPILEPTIFORM FITS.

Dr. CECIL E. REYNOLDS (Los Angeles) writes: I have just read "H. C. B.'s" inquiry in the JOURNAL of November 8th, 1924, asking advice for the treatment of epileptic fits of almost daily occurrence in a child of 5. He does not describe the attacks, nor state which way the head and eyes deviate at the beginning and during the attack, nor whether the fit begins with tonic emprostotonus, opisthotonus, or pleurothotonus. Generally speaking, in a case of this kind, if the stools have been found negative for parasites and ova, a subtemporal decompression reveals great excess of subdural and subarachnoid fluid, and sometimes cures the patient. If this does not suffice, but has definitely established a diagnosis of external hydrocephalus, a two-stage suboccipital decompression will probably cure. Many of these cases follow acute fevers, such as tonsillitis, measles, and whooping-cough. May I refer "H. C. B." to my communications in the BRITISH MEDICAL JOURNAL of July 16th, 1921, and June 17th, 1922, recording similar cases which defied all medical treatment and were progressing to death. The patient described in July, 1921, is still perfectly well, as also two previous and several subsequent patients. In 1921 I suggested this was a rare cause of seemingly "idiopathic" epilepsy, but now I know it is common. Operation is the only recourse. The fluid must be allowed to drain into the tissues very slowly, and as little lost at operation as possible; sudden release is very dangerous. It is safer merely to prick the dura at the first operation, when fluid is seen to spurt out six inches or more. It can then be fully opened five days later and the dura tucked under the muscles to act as a drain; no catgut should be used, only fine silk. Diagnosis may be impossible before the fluid is found when operating, but spinal puncture may give a clue both by its pressure and by the temporary benefit produced; this, however, is very deceptive. In external hydrocephalus the fit usually begins with tonic emprostotonus, and is followed by clonic jerking of the head and eyes to the right in right-handed and to the left in left-handed children. This is not nearly so constant in internal hydrocephalus. Between the fits the earliest physical sign is a slight alternating internal strabismus, and later a slight weakness of that side of the mouth innervated by the more highly educated hemisphere. Any tendency to turn in one foot in walking should be noted.

## INCOME TAX.

## Licence for Male Servant.

"B. A.'s" chauffeur is wholly employed in connexion with his medical practice; is he liable to the male servants' tax of 15s.?

\* \* In the circumstances quoted the chauffeur is not, in our opinion, employed in a personal, menial, or domestic capacity, and no licence duty is payable.

## LETTERS, NOTES, ETC.

## RADIUM THERAPY IN MALIGNANT DISEASE.

In our review of the annual report of the Medical Research Council last week (p. 124) the statement made with regard to the British Empire Cancer Campaign was confused. In order to put the matter right the best course will perhaps be to quote in full the paragraph from the section of the report headed "Radium Therapy in Malignant Disease."

"Important aid is now being brought to the work by two allocations of funds by the British Empire Cancer Campaign. One of these is for the purchase of a further five hundred milligrams of radium salt to enable the investigations to be extended in certain urgently desirable directions. The other is for the initial and current cost of an emanation service to be established at the Middlesex Hospital in connexion with the radium already supplied by the Council. For this purpose about a gram of radium salt lent by the Council is being placed in solution to provide a source of emanation for use at the different centres supplementing the treatment by use of the radium salt itself."

## THE MOTOR DRIVER'S REGISTRATION BOOK.

THE Automobile Association recently brought to the notice of the Home Secretary the conviction of a motorist by the Ouse and Derwent Bench on two charges—(1) failure when on the road to produce his registration book upon the request of a police officer, and (2) the omission of the make and horsepower of the car from the licence affixed to the car. As regards the first charge, the registration book itself states: "Keep it in your car, and place it not on the car." As regards the second charge, the licence affixed to the car was in the form issued to the motorist by the particular licensing authority, and the fact that certain words had been omitted was clearly no fault of the motorist. Nevertheless, in each case the motorist was fined £1. The Automobile Association is now informed by the Home Secretary that he has recommended the remission of the fines imposed. We should think so!

## SURSUM CORDA.

Dr. GEORGE C. STEWART (Falkirk) writes: If any of your readers is suffering from mental distress from any cause I can heartily recommend to him Mr. Selwyn Image (who is of Thomas Bewick, recently deceased) found so efficacious—namely, a reading of that book. It breathes the very spirit of homely common sense and sound mental health, and the woodcuts are a perpetual joy. Although Bewick's father refused medical attendance during his last illness, and threatened to throw any drugs which his son offered to

send him behind the fire, Bewick himself considers that he was fortunate in having been intimate with members of the learned professions, and pays a true tribute to our profession when he writes—"On taking a comparative survey of the whole, I cannot help giving a preference to medical men; for, besides their learning and attainments in common with other professions, they appear to me, generally, to be further removed from prejudice, more enlightened, and more liberal in their sentiments than the other labourers in the vineyards of science and literature." While the profession maintains this position in the opinion of hard-headed, cultivated men of the Bewick type (the best English yeoman class), we need not fear the machinations of any Government.

## ANTE-OPERATIVE SKIN DISINFECTION.

SIR JOHN O'CONOR, K.B.E., M.D. (Buenos Aires), writes: The recent correspondence about the danger of picric acid inspires me to beg leave for space to pay tribute of homage to tincture of iodine (I.P.), which (apart from abdominal work, in which I found it a grave peritoneal irritant) has afforded me most gratifying results. After many years' hospital experience I can, in all sincerity, testify that in all neck and breast operations, in bone and joint surgery, as well as in serotal, vaginal, and rectal procedures, tincture of iodine pigment is an ideal method of skin disinfection, and does not, if employed as sole chemical, excite any subsequent skin irritation once in every three hundred cases. If it is used in conjunction with any other chemical, notably mercury, anything may happen, consequently whenever an operation case goes septic care must be taken to remove all visible iodine (with alcohol) before employing any fomentation or other chemical disinfectant. For abdominal skin disinfection I have only one formula. The skin of the part is gently scrubbed and washed with sterilized nail brush, soap, and hot water for ten minutes, then washed with alcoholic perchloride of mercury lotion (1 in 1,000) for five minutes, covered with sterilized lint wrung out in aqueous "perchloride" lotion (1 in 3,000, wool, and bandage. When the latter are removed, on the operation table, a final wash is given with alcohol mercurial lotion.

## TUBERCULOUS DISEASE OF THE STERNUM.

Dr. B. R. CLARK (Forster Green Hospital for Consumption, Belfast) writes with reference to the memorandum by Dr. Johnson (BRITISH MEDICAL JOURNAL, January 10th, p. 71): I cannot find any evidence of tuberculosis either in the clinical report or in the post-mortem findings. The history, signs, symptoms, and post-mortem changes of Dr. Johnson's case seem to me to suggest pyaemia rather than tuberculosis.

## BRIGHTER BIOCHEMISTRY.

THE second annual issue of *Brighter Biochemistry*, the illustrated journal of the Biochemical Laboratory, Cambridge, calls to mind a tag from *The Pirates of Penzance*: "Oh! hero is love, and here is truth, and here is food for joyous laughter!" The "love element" is certainly buried as deep as the more abstruse words in a cross-word puzzle, but Fig. 2 indicates the difficulty of separating the affinity-loving A and B particles—a task described as "thermodynamically impossible." A certain antimetaphysician bias is discernible in the ballad about Jane "who had no bacteriological technique, and so perished miserably," and in the tragedy of Cuthbert, who worked next door to "a most untidy feckless maid," who mixed such labels as "saccharose puriss" and "KCN." Under the heel of "truth" must be classed the editorial "and also perhaps the opening poem, or occupies a page in my theme: 'I write to say I will not write.' The third ingredient, 'joyous laughter,' is supplied in abundance, even though the high spirits of Cambridge biochemists are sometimes expressed in language too highly technical for readers of an older generation. But most of us can appreciate the humour of such a poem as that beginning—

I cannot synthesize a bun  
By simply sitting in the sun;

and ending—

There is a certain  
Faintly  
Can most effective synthesis.

We understand that *Brighter Biochemistry* may be obtained from the Editor, Biochemical Laboratory, Cambridge, for 2s. 6d.

## ERRATA.

MR. W. H. KELSON asks us to correct certain slips in the abstract of his paper on "Some osseous growths of the nasal and adjacent bones," published in the JOURNAL of December 27th, 1924 (p. 1197). The word "profuse," qualifying osteitis, should be "diffuse," and the word "boneless," applied to the swelling described by Douglas Guthrie, should be "bony." Mr. Kelson's case was shown in 1908 to the Laryngological Society of London, not the Royal Society of Medicine; and the diagnosis of Westmacott's eight cases, described in 1913 as being "osteitis fibrosa," should be attributed to Professor Knaggs, not to Westmacott.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 48.

# Lectures ON THE SYMPATHETIC INNERVATION OF STRIATED MUSCLE.

BY  
THE LATE JOHN IRVINE HUNTER, M.D., CH.M.,  
CHALLIS PROFESSOR OF ANATOMY IN THE UNIVERSITY OF SYDNEY.

## EXPLANATORY INTRODUCTION

BY  
G. ELLIOT SMITH, M.D., F.R.S.\*  
PROFESSOR OF ANATOMY, UNIVERSITY COLLEGE, LONDON.

[When Professor Hunter arrived in England last November he was invited by the University of London to give three advanced lectures in anatomy, which were to have been delivered in the second week of December: but the large audience that assembled to hear the first lecture were informed of the grave illness to which he succumbed two days later (see *BRITISH MEDICAL JOURNAL*, December 20th, 1924).

He had been looking forward with the keenest interest to the delivery of these lectures, because they would have provided him the opportunity for clearing away the misunderstanding of his work and for demonstrating the adequacy and reliability of his evidence and the inferences he had drawn from it. In particular he was anxious to explain the scientific principles that should guide the surgeon in the selection of patients for the operation that he had devised (in collaboration with Dr. Norman Royle) for the relief of certain patients subject to spastic paraplegia—namely, those whose voluntary control of muscular actions was unimpaired except for the interference resulting from an exaggeration of what Sherrington calls "plastic tone"; and it had been his intention to describe the surgical procedure in so far as the reasons for the choice of the rami to be cut were concerned.

In the third lecture he proposed to discuss the discordant conclusions that had been drawn by different physiologists and surgeons respectively from their experiments (especially in the cat) and operations on the sympathetic in human patients, and to give the explanation of this apparent lack of consistency.

Finally, he intended to deal with the wider scientific bearings and the physiological, pharmacological, and chemical.

This much the compiler of these reports gathered in conversation with Hunter, who, unfortunately, had not prepared any manuscript of the three lectures he had intended to give. It had been his intention, as was his usual custom, to speak without notes, and apart from these conversations and the large series of lantern slides and cinematographic films, he has left nothing in the form of lectures. Yet the subject is so important in its scientific bearings, and the need for some explicit guide to surgeons is so urgent, that the attempt has been made to do what Hunter had intended to do, and to publish the reports.

The compiler has done nothing more than select passages from Hunter's published and unpublished works and endeavour to give a connected and consistent account of his results. In addition to the three memoirs published in the *Medical Journal of Australia* (January 26th, June 14th, and September 27th, 1924), in *Brain* (August, 1924), and in *Surgery, Gynecology and Obstetrics* (December, 1924), the compiler has in his hands the manuscripts of three unpublished memoirs of Hunter's on this subject, as well as the shorthand reports of discussions in which he took part at Brooklyn and Philadelphia in October. Moreover, Hunter had intended to make use of the information provided by Orbeli and his collaborators, of which an account was given by Dr. W. Horsley Gault in the *BRITISH MEDICAL JOURNAL* of September 20th, 1924 (p. 533).

\* By whom the lectures were delivered at University College, London, January-February, 1925.

While the statements made in the following pages are Hunter's, any faults of arrangement or of literary form are to be attributed to the compiler. Discussing the problem which Hunter sets out to solve in these lectures Pechlaring<sup>1</sup> twelve years ago wrote: "The most direct investigation of the mechanism of muscular contraction will be afforded by microscopic study: but, unfortunately, we must wait for a happy inspiration to reveal the road to follow." The compiler of these lectures is convinced that Hunter has got the "happy inspiration."]

## LECTURE I. THE DUAL INNERVATION OF STRIATED MUSCLE.

In his classical memoir on postural activity of muscle and nerve Sir Charles Sherrington<sup>2</sup> makes the statement that: "The existence in various invertebrata of muscles separately differentiated for execution of movements and for maintenance of posture respectively seems without parallel in the skeletal musculature of vertebrates. In the latter, one and the same muscle is used for the two purposes, though some muscles are predominantly concerned with the one, some with the other function." Discussing the same subject, the late Sir William Bayliss was frankly sceptical. Thus, in his *Principles of General Physiology* he says: "It is not easy to understand how two fibres of different function and different innervation could coalesce with retention by the combined cell of both kinds of innervation." The chief aim of these lectures is to justify Bayliss's attitude of scepticism by showing that no such coalescence does in fact occur, for the muscular tissues of vertebrates are at least as highly differentiated in structure and function as those of invertebrates.

In his discussion of the sympathetic innervation of striated muscle that led to this expression, Bayliss admits that "two kinds of function are performed by two separate kinds of muscle fibres, as in the auricle of the tortoise, or by separate muscles, as in the mollusc"; yet he goes on to express the commonly accepted view in these terms: "But in other cases, as in the vertebrate bladder or in that of voluntary muscles, the same fibres undertake both functions, so far as can be made out." I shall first give reasons for the conclusion that the same fibres do not undertake both functions.

The evidence in support of this conclusion is provided (a) by the appreciable structural differences in the two kinds of fibres in striated muscles; (b) by different modes of innervation of the thick and the thin fibres; (c) by the totally different effects produced by cutting the medullated (somatic) and the non-medullated (sympathetic) nerves passing respectively to the thick and the thin fibres; and (d) the interpretation of the effects of stimulation of the sympathetic or the influence of adrenaline, veratrine, etc., such as Oliver and Schafer (1895), Cannon and Nieu (1913), Cannon and Cattell (1916), and Orbeli and his collaborators (1922-24), amongst others, have recorded.

## THE ANATOMICAL EVIDENCE OF TWO DISTINCT KINDS OF STRIATED MUSCLE FIBRES.

Forty years ago Ranvier called attention to the differences in structure in red and white muscles, and since then he and many others have examined the evidence more fully and correlated the anatomical facts with differences in function of the two types of muscle. In his *Textbook of Microscopic Anatomy* Sir Edward Sharpey-Schafer has summed up the evidence so clearly that I cannot do better than quote his statement:

"In the rabbit, as pointed out by Ranvier (1837 and 1889) and Krause, certain of the voluntary muscles present differences in appearance and mode of action from the rest. Thus, while most of the voluntary muscles have a pale aspect and contract energetically when stimulated, some . . . are at once distinguished by their deep red colour, as well as by their slow and prolonged contraction when stimulated. When subjected to microscopical examination it is found that in the red muscles the fibres are more distinctly striated longitudinally and the transverse striae are more irregular than usual. The muscular fibres are generally finer (thinner) than those of the ordinary muscles, and have a larger amount of sarcoplasm. The nuclei are more numerous and are not confined to the inner surface of the sarcolemma, but occur scattered in the thickness of the fibre as well. There is also a difference in the blood supply of the two kinds of muscle. . . .

"A similar difference between red and pale muscles may be also seen in the rays amongst fishes. In other animals the distinction is not found as regards whole muscles, although it may affect individual fibres of a muscle. This is the case, as shown by Klein, in the diaphragm, in which in many of the fibres there are numerous nuclei, and these are imbedded in protoplasm (sarcoplasm), which forms an almost continuous layer underneath the sarcolemma. The distribution of the two kinds of fibres in different muscles has been especially investigated by Gruetzner (1884)."

The contrast between the structure, mode of innervation, and functions of the two types of muscle, as well as the striking differences in their respective liability to fatigue, have been emphasized by many other investigators; and I might mention the memoirs of Dr. John Hay<sup>5</sup> and Dr. Ffrangcon Roberts<sup>6</sup> as important contributions to the evidence and interpretation of this interesting fact.

These records establish quite definitely the fact that there are two kinds of striated muscle, distinguished by contrasted morphological and physiological properties. But it is important not to confuse red and white muscles with the thin and the thick fibres respectively. While it is established that the sluggish red muscle is composed mainly of slender fibres innervated mainly by fine nerve fibres, and the briskly reacting and easily fatigued white muscle of thick fibres innervated by large medullated fibres, it yet remains to be decided whether or not all striated muscles are composed of both kinds of fibres—obviously, of course, in very different proportions in the various muscles.

It is right that some reference should be made here to Gruetzner's insight when, in 1887, he put forward his brilliant suggestion as to the real meaning of the work of Ranvier and his collaborators. Gruetzner attempted to correlate the physiological phenomena exhibited by skeletal muscle with the then recent developments in knowledge of the histology of muscle. He developed the idea of an "intrinsic support" within the muscle, enabling one contraction to be superposed upon another. He put forward the view that some muscle fibres were responsible for the contractions and others for the "intrinsic support." If some muscle fibres are supplied by somatic nerves and the remainder by sympathetic nerves only, the general principle of the functional duality theory of Gruetzner would, in the light of the experimental analysis undertaken by Royle and me, be established.

#### DIFFERENCES IN THE INNERVATION OF THE TWO KINDS OF STRIATED MUSCLE FIBRE.

It was Kulchitsky's demonstration<sup>7</sup> of the fact that "the medullated and non-medullated fibres never terminate in the same muscle fibre" that impelled me to investigate by experiment the influence of the non-medullated nerves, which Boeke had clearly proved to be sympathetic, upon muscular function. During the year 1922 I was fortunate in being able to work with Professor Kulchitsky at University College, London, and to be permitted to take back to Sydney (early in 1923) some of his beautiful preparations of the endings of the medullated and non-medullated nerves in striated muscle, the description of which he did not publish until a year later. When I returned to Australia Dr. Norman Royle (with whom I had previously collaborated in an experimental investigation of the effects of transverse lesions of the goat's spinal cord) consulted me with reference to the inadequacy of the surgical operations to relieve spastic paraplegia. We studied Kulchitsky's preparations of nerve endings and the review of the present state of our knowledge by our former master, Professor J. P. Wilson,<sup>8</sup> and decided that, as certain of the muscle fibres were innervated solely by the sympathetic, some definite effect ought to be produced by cutting the sympathetic nerves going to limb muscles.

Hence we devised the series of experiments, and eventually the surgical operations which I shall discuss in the second and third lectures. But before doing this it is essential that I should consider the problem of the nerve endings, which is a matter of fundamental importance in this inquiry.

It has already been mentioned that as early as 1824 Ranvier called attention to the fact that there are two kinds of striated muscle fibres—one slender and rich in sarcoplasm with irregular transverse striae, the other thicker and much more energetic. Five years earlier (1879) Tschirner had recorded that the thinner fibres are innervated by non-medullated nerves with grape-like endings, whereas the thick fibres are supplied by medullated nerves with end-plates such as Kuhne had described. This important discovery attracted little attention because Tschirner supposed the fine muscle fibres with their non-medullated nerves were merely embryonic forms of the larger fibres with medullated nerves.

In 1902 Perroncito confirmed Tschirner's observations that the different kinds of nerves (medullated and non-medullated respectively) were not supplied to the same muscle fibre. But since then Boeke has put forward the claim that both kinds of nerve may end in the same muscle fibre; and for more than ten years experimenters and morphologists have been trying to harmonize the facts of their fields of investigation with Boeke's statement.

Before giving the reasons for dissenting from these views, which are opposed to the observations recorded by Tschirner, Perroncito, Kulchitsky, and others, reference must be made to Boeke's important demonstration of the fact that the non-medullated nerve fibres proceeding to striated muscle are really sympathetic. By the application of the experimental method to the elucidation of morphological problems he was able to show that the non-medullated nerves in question are the terminal portions of grey rami communicantes which arise in the thoracic-lumbar ganglia of the sympathetic cord. Boeke found in cats that three weeks after section of the nerves to certain of the eye muscles near their origin from the brain stem,

many non-medullated fibres had resisted degeneration. He rightly concluded that these were sympathetic fibres from the cervical sympathetic chain which had been transferred to the eye muscle nerves distal to the point of experimental section of these nerves. Boeke performed the converse experiment of removing the superior cervical ganglion, but, beyond the fact that he was able to record the impression that the non-medullated fibres were fewer in number at the end of two weeks, this experiment was unsuccessful. Agdnhr, on the other hand, after removal of the ganglion stellatum in a cat, was able to find, on killing the animal six days later, the remains of degenerated non-medullated nerves supplying skeletal muscles of the fore limb. It must be accepted, therefore, that some at least of the non-medullated fibres found supplying skeletal muscle take their origin from the vertebral ganglia of the ganglionated sympathetic chain. To employ the terminology of Langley, who confines the term "sympathetic" to the thoracic-lumbar outflow, the skeletal muscles receive post-ganglionic non-medullated fibres of the sympathetic nervous system by way of the grey rami communicantes. In addition, of course, this muscle receives the ordinary cerebro-spinal nerve fibres of somatic origin. In this sense skeletal muscle has a double innervation.

But if Boeke and Agdnhr have rendered this great service of establishing the origin of the sympathetic fibres to striated muscle—a discovery which necessitates a new orientation of our ideas of the sympathetic and stultifies the definition of the sympathetic system still found in all

FIG. 1.—To illustrate Kulchitsky's demonstration of the dual innervation of striated muscle—large fibres innervated by medullated nerves ending in muscle plates (M. Pl. I and Acc. M. Pl.) and slender fibres innervated by non-medullated (sympathetic) nerves with so-called "grape-like" terminations (Pl. II).

our textbooks—they have also introduced an element of discord by their claim that both kinds of nerve end in the same muscle fibre.

Limitations of space make it impossible to give an adequate account of my reasons for rejecting the opinion of Boeke on this matter. In collaboration with my colleague, Dr. Oliver Latham, I have carefully examined the mode of ending of the nerves proceeding to the limb muscles of the goat and fowl, the animals used by Dr. Royle and myself in our experimental work. A full account of our results will soon be published; all I need say at present is that in no case were we able to discover a muscle fibre receiving both kinds of nerve fibres. In this respect our results confirm those previously obtained by Kulehitzky and the pioneers Tahiriev and Perroncito. Kulehitzky is not willing to admit that any of the grape-like endings of the non-medullated nerves are hypolemmal, whereas Tahiriev says they are definitely hypolemmal. Latham was able to show that there are two kinds of nerve endings on the slender muscle fibres—those of the efferent nerves, which are the grape-like hypolemmal terminations, and others, presumably afferent, epilemmal endings. It is interesting to note, in confirmation of these claims, that Agduhr states that he has Bielschowsky preparations to demonstrate that in addition to hypolemmal terminations, "there are also epilemmally situated sympathetic terminal plates in the limb musculature." It is evident, therefore, that efferent (hypolemmal) and afferent (epilemmal) sympathetic nerve endings are distinguishable from one another. In the next lecture I shall demonstrate the experimental proof of the existence of both afferent and efferent fibres from the sympathetically innervated muscle fibres.

In collaboration with Mr. R. E. Murray, B.Sc., of the University of Sydney, I have made a critical examination of the evidence cited by Boeke and Agduhr in support of their claim for the double innervation of individual muscle fibres. Our memoir on this important issue is ready for publication with a series of illustrations. At present I shall quote merely certain passages from the full statement. Boeke established the existence of a plexus of non-medullated nerve fibres supplying skeletal muscle, which appeared to be quite independent of the ordinary medullated nerve fibres. He termed this system of fibres together with their terminations on striated muscle fibres "accessory," and in 1913 suggested that this system was sympathetic or autonomic in character. He supplemented his morphological researches by experimental investigations, which he summarized in 1917 in an extensive memoir. See also his London lecture published in *Brain* (1921). This work proves beyond doubt the validity of his contention that the extrinsic striated muscles of the eye are innervated by sympathetic as well as by the cerebral motor nerves. But at the same time his results raise a doubt whether he is right in describing all the fibres and endings which he originally termed "accessory" as being sympathetic in origin.

The most striking result which points to the improbability of Boeke's contention is provided by the fact that a marked difference in the histological picture of the nerve supply to the extrinsic muscles of the eye is to be seen after section of the cerebral motor nerves to these muscles, according to the time after the operation at which the examination of the muscle is made. In some cases he allowed a short period for degeneration (three to five days), and in others a longer period—for example, three weeks. After a short period specimens stained by the Bielschowsky method revealed that all the medullated fibres and their associated end-organs were undergoing degeneration. But the non-medullated "accessory" system was so well represented that apparently at least one "accessory" nerve ending was to be seen on each muscle fibre. In similar preparations of material in which degeneration had proceeded for the longer period, however, the greater number of these non-medullated nerve fibres which resist degeneration altogether are derived from sympathetic communications to the motor cerebral nerve which join the nerve distal to the site of section. On the other hand, the degenerated fibres and terminations of the

"accessory" system of Boeke obviously belong to another category. Boeke's explanation of the failure of these fibres to resist degeneration is that they are cranial autonomic in origin; but, as Wilson points out, he does not indicate in which ganglion the cells providing these non-medullated fibres are situated. Wilson also calls attention to the fact that, in any case, the section of the motor cerebral nerve is close to the brain stem, and the ganglion should remain uninjured, and therefore degeneration whether Boeke has established beyond doubt that the point of degenerating fibres are actually non-medullated rather than finely medullated fibres whose sheaths have already suffered degeneration. Nor does Boeke's converse operation of removing the superior cervical sympathetic ganglion establish that all the "accessory" fibres are sympathetic in origin. For the entire system did not disappear, though Boeke thought the fibres were fewer in number.

These anomalies in Boeke's interpretation of the origin of the "accessory" system undermine his contention that every individual muscle fibre receives both a sympathetic and somatic nerve ending, for any given case cited by Boeke may well be an example of two somatic endings, and not of double innervation in the sense in which that term is used in this lecture.

In later experiments by Boeke and Dusser de Barenne (upon the double innervation of the intercostal muscles of the cat) no mention whatsoever is made of the relation of the somatic and sympathetic endings to each individual muscle fibre. This work proves only that the intercostal muscles as a whole receive both sets of nerves.

In this respect the evidence of Agduhr is of great importance. This author investigated experimentally the result of partial denervation (somatic or sympathetic) of the muscles of the fore limb of the cat. After removal of the ganglion stellatum he succeeded in observing in Bielschowsky preparations of the brachial musculature, secured six days after the operation, the remains of degenerated non-medullated nerves. He also cut the last four cervical and the upper two thoracic nerves in the intervertebral foramina between the spinal ganglia and the point of divergence of the white ramus communicans. He killed the animal, the histological investigation of which is described in detail, five days after the operation; but he records finding similar appearances after a period of ten days. He observed that all the medullated fibres (motor and sensory) had undergone degeneration. On the other hand, many non-medullated fibres were seen to be intact; they were lying along blood vessels and were partly bound up with degenerated medullated fibres.

The point of interest in the present discussion is that Agduhr describes a single muscle fibre which shows two hypolemmal end-plates upon it. One of these is degenerated and therefore the termination of a somatic nerve fibre. The other receives a non-medullated nerve fibre. In consequence of this Agduhr describes this as an instance of a single muscle fibre receiving both a somatic motor and a sympathetic termination. He records, however, that the plate regarded by him as being sympathetic in origin had a large extension on the muscle fibre, and on account of this approached in character the somatic motor terminal plates. Further, he states that the distance of the two plates from one another is "such as one finds in a spinal plurisegmental innervation of the separate muscle fibres." If we add to these considerations the short period of degeneration allowed in the specimen figured by Agduhr (five days), in the light of the fact that Boeke found that non-medullated fibres may be seen for a considerable period when actually undergoing degeneration, no proof is provided that the muscle fibre described is actually innervated by both somatic and sympathetic nerve endings. It is possible that the second plate is the ending of a non-medullated collateral of a medullated fibre rather than an independent sympathetic termination.

Kulehitzky, whose careful work stimulated the present investigation, has described, for instance, such additional plates provided by collaterals. Dr. Oliver Latham of Sydney has found a beautiful example of a non-medullated collateral of a medullated nerve fibre ending hypolemmally

in precisely the same way as the fibre which is figured by Agduhr. This collateral arises at a considerable distance from the site of termination of the medullated fibre, and the distance between the two plates is comparable to that which separates the endings in Agduhr's preparations.

Thus the contention of Boeke and of Agduhr that each muscle fibre receives a double innervation cannot be confirmed; nor does it agree with the evidence of other observers. Obviously the experimental method should afford evidence to settle the question whether individual muscle fibres are innervated by both somatic and sympathetic nerves. For this reason the muscles of the hind limbs of some of the goats employed by Dr. Royle for excision of the lumbar sympathetic chain on one side were histologically examined. The normal side was used for control. The preparations from the operated side showed in transverse section a number of small muscle fibres which were in marked contrast to the fibres of average size in the same preparation which were apparently normal. These diminutive fibres were too numerous to be accounted for as the conical or pointed terminations of normal muscle fibres. Further, the connective tissue (endomysium) between the individual muscle fibres has increased in amount. This was specially noticeable in a preparation secured by killing the animal six months after performing the operation.

Conversely, the somatic innervation may be removed and the sympathetic nerve supply to the striated muscle left intact. The wing of the domestic fowl readily provides a preparation of this kind. Both the anterior and posterior nerve roots of the lowest three cervical nerves were severed without injury to the cervical sympathetic ganglia or the white ramus communicans which emerges at the level of the first thoracic segment. In this way the wing was deprived of the major part of the somatic nerve supply. Seventy days later the bird was killed. Post-mortem examination revealed that the operation had been successfully performed and the cervical sympathetic trunk was found intact. On microscopic examination large numbers of degenerated medullated nerve fibres were found in a preparation from the flexor muscles of the forearm. These muscles when stained in haematoxylin and cut in transverse section showed a marked contrast to the corresponding muscles from precisely the same point of the normal wing, which were treated in exactly the same manner. The individual muscle fibres of the normal muscle showed remarkably little variation in size throughout the preparations. The muscle of the wing from which the somatic innervation had been removed was in marked contrast to this. Many of the fibres were normal in size or slightly larger than the largest fibres of the normal muscle. These appeared in groups, and some fasciculi were entirely composed of them. Other fibres showed a marked diminution in diameter to approximately 33 per cent. of that of the muscle fibres of average size. These also occurred in groups, and in some cases they formed entire fasciculi. Other fasciculi were made up of groups of both normal and diminutive fibres lying in juxtaposition. The connective tissue of the muscle was increased in amount; a few masses of young connective tissue cells were in evidence between the bundles, and the endomysium was slightly more developed than in the control specimen.

It is firmly established that diminution in the size of all the muscle fibres follows complete denervation. The work of Willard and Gran on white mice may be cited as evidence of this. The leg muscles on one side were deprived of their innervation. The corresponding muscles of the other side were used as a control. Specimens were investigated showing atrophy of from three to sixty-three days' duration. These authors found a progressive decrease in fibre diameter, this change being unaccompanied by any change in the number of fibres. They describe the decrease in diameter as being "up to 68 per cent." During the period under observation there was no connective tissue proliferation between the muscle fibres. The difference in the findings of Willard and Gran and our observations in regard to the proliferation of connective tissue is no doubt accounted for by the fact that a partly denervated muscle is not entirely inactive. In the case of sympathetic

denervation, which removes plastic tone, increase of fibrous tissue no doubt renders the muscle more efficient in maintaining a position imposed by active movement or by selective reflex activity. When contractile tone is removed by somatic denervation only a very slight increase of connective tissue occurs over a period of sixty days. The support of the wing during this period had therefore been provided practically entirely by the healthy muscle fibres which exhibited plastic tone.

The conclusion can be drawn from the experimental facts that partial denervation—somatic or sympathetic—affects some fibres and not others. This confirms the evidence obtained from a study of gold chloride preparations. On the basis of innervation, therefore, skeletal muscle is found to consist of two sets of fibres. In the experimental preparations the fibres of each set tend to occur in groups. This is in accordance with the findings of Latham in gold chloride preparations of the skeletal muscle of the domestic fowl and goat, that a considerable number of fibres, either receiving the endings of only non-medullated fibres or of only medullated fibres, tend to occur in

proximity to one another. Even in teased preparations a group of as many as seven muscle fibres may receive non-medullated fibres, while no terminations of medullated endings may be visible in the same field. Such an appearance may have been a source of error in the past in suggesting that every muscle fibre receives a sympathetic innervation. The possibility arises, therefore, that the mode of innervation of skeletal muscle is that any individual muscle fibre receives one motor nerve ending—somatic or sympathetic as the case may be—and not both motor endings, and that each type of muscle fibre occurs in groups.

As an instance of the presence of a single type of motor innervation it may be recalled that the muscle fibres of muscle spindles receive sympathetic motor terminations. The existence of a double motor innervation to these muscle fibres, although suggested by Perroneito, has not been confirmed. Recently, on the other hand, Agduhr has found sympathetic terminations on these intrafusal fibres in the limb muscles of the cat. Kulchitsky and Dart have found these endings in relation to the fibres of the muscle spindles of the python. Dart is in error in regarding the fibres as being finely medullated, but he shows clearly that the endings are associated with diminutive sole plates. This

FIG. 2.—Diagram to indicate the three constituent elements of striated muscle, slender fibres, thick fibres, and muscle spindles, and their innervation. The afferent sympathetic fibre from the spinal cord to the muscle is not connected to posterior root ganglion; the afferent fibre is not connected to posterior root ganglion by an efferent non-medullated nerve.

type of ending has already been described in this lecture as being sympathetic efferent in character. The intrafusal fibres seem, therefore, to have a single efferent innervation which is sympathetic in origin. This is in itself a point of great importance, for it suggests that other fibres may be similarly innervated.

I suggest, therefore, that the skeletal muscle of vertebrates consists of two sets of muscle fibres disposed in groups each with its own specific innervation, and, consequently, its own specific function, the experimental investigation of which will be discussed in the next lecture. I shall then endeavour to establish the proof of the following claims. The fibres receiving somatic nerve endings are concerned in shortening as the result of voluntary and of reflex activity, and in isometric contraction during the continuation of the voluntary movement and for what Langelaan<sup>1</sup> calls "contractile tone." They are comparable to what Sherrington calls the "movement muscles" of invertebrates. Other fibres, innervated by the sympathetic system, are first inhibited and then lengthened and shortened during these processes, and remain at the new length passively imposed upon them. In other words, these fibres exhibit what Sherrington has called "plastic tone." They are comparable to the "fixing muscles" of invertebrates. During movement these fibres aid in supporting the weight of the part. At the termination of movement they take part in maintaining the position attained as the result of the movement.

Further, some of the "fixing muscle" fibres appear to be included within a sheath to form the special sense organs (muscle spindles) which transmit afferent impulses to the central nervous system by means of somatic sensory fibres. The degree of lengthening and shortening imposed upon these intrafusal fibres is maintained by the influence of their sympathetic innervation. Epilemmal sympathetic endings found on other fibres that receive also a sympathetic motor innervation probably constitute in a similar way sympathetic proprioceptor organs.

All the evidence related above in regard to the exact mode and the function of the double innervation of skeletal muscle indicates that the differentiation of muscles into "movement" and "fixing muscles," which is so apparent in some invertebrates, is not lost in vertebrates. These two muscle systems of invertebrates are represented as small skeletal groups which mingle together to constitute the skeletal muscles of vertebrates.

From the standpoint of physiology the existence of such an arrangement would readily account for the marked similarity in the behaviour of the "catch" mechanism of invertebrates and the activities of skeletal muscle in maintaining posture. In reviewing the points of comparison between the two processes, Bayliss recalls the suggestion of A. V. Hill that a more efficient mechanism of maintaining a weight must be exhibited under natural conditions than that displayed by the sartorius muscle of the frog when its nerve is stimulated by induction shocks. He compares also the process of inhibition of the "catch" mechanism (von Tscholl) with that of the tonic contraction of skeletal muscle during decerebrate rigidity (Sherrington); and he calls attention to the existence of an extremely low rate of metabolism during the activity of the "catch" mechanism (Parnas, Bethe) and of skeletal muscle in the state of decerebrate rigidity (Roaf, Lovatt Evans). If separate muscle fibres exist in vertebrate skeletal muscle for the fixation of posture and for active and reflex shortening and for isometric contractions of the muscle, the differences in manifestations of these activities of inhibition during the groups will be readily comprehended.

From the pathological standpoint this view introduces a line of attack to relate the symptomatology and pathology of such diseases as myotonia atrophica, the muscular dystrophies, and myasthenia gravis. In poliomyelitis it has long been known that sometimes the sympathetic ganglia partake of the degeneration found in the lower somatic motor nerve system. Such cases are, no doubt, those in which the tone of the muscle affected is completely lost. In other cases, in which there develop rapidly structural deformities due to the tendency for the limb to remain fixed in posi-

tions imposed upon it, the sympathetic innervation probably remains intact. Further, according to this conception, the operation of sympathetic ramisection for spastic paralysis consists in removing the nerve supply to the fixing muscle fibres only. All the movement fibres remain entirely unaffected. This, no doubt, accounts for the efficiency of the partly denervated muscles after long periods of time—for example, twelve months. On the other hand, according to the prevailing theory of the existence of the double innervation of each individual muscle fibre, the operation would entail partial loss of the nerve supply of each fibre of the muscle; or, more precisely, that the sarcoplasm of each muscle fibre is deprived of its nerve supply. This is unlikely in view of the unimpaired activities of reflex and of active shortening of the muscles which remain for long periods after the operation.

## PER-URETHRAL OPERATIONS FOR PROSTATIC OBSTRUCTION.

BY  
KENNETH M. WALKER, F.R.C.S.,  
SURGEON IN CHARGE GENITO-URINARY DEPARTMENTS, ROYAL  
NORTHERN HOSPITAL, AND MILLER GENERAL HOSPITAL  
FOR SOUTH-EAST LONDON.

The introduction of suprapubic prostatectomy in 1901 led almost immediately to the abandonment of the various palliative methods of treatment that had previously been tried with indifferent success. Since that time prostatectomy has grown in popularity, so that nowdays it is regarded by many surgeons as a routine method of treatment to be carried out in all cases of enlargement, except where some special contraindication exists. With improved technique the mortality of the operation has steadily diminished, so that patients who thirty years ago would certainly have been condemned to catheter life are now subjected to operation. But great as has been its success, prostatectomy must still be regarded as a serious operation, and one that, even in the hands of the most competent, is attended by a comparatively high mortality rate. In view of this and of the fact that there must exist cases in which prostatectomy is unjustifiable, it may not be out of place to describe certain less drastic procedures which, in suitable cases, give excellent results.

### Objections to Partial Removal of the Prostate.

Three criticisms are usually levelled against any operation that fails to effect a complete removal of an enlarged prostate: first, that the treatment is likely to fail in its object; second, that even when it succeeds the results are temporary; and third, that as an apparently innocent prostate may microscopically show malignant changes it is unwise not to remove it. The first two of these objections will be discussed more fully later. Suffice it for the moment to state that the whole success of partial operations on the prostate depends on a judicious selection of cases, and that failures are generally due to an ill advised attempt to tinker with a large prostate that is amenable only to total enucleation.

With regard to the third objection, as long ago as 1900 Albarran and Hallé called attention to the fact that a certain number of prostates which clinically appeared to be examples of innocent enlargement showed malignant changes when examined microscopically. This observation has since been confirmed and a figure approximating to 14 given as the percentage of cases in which these changes are found. From this it has been argued that as it is impossible to be sure that an enlarged prostate is pathologically innocent the wisest procedure in all cases is to carry out total prostatectomy. This argument for the wholesale removal of enlarged prostates would be unanswerable but for two facts—the first, that total prostatectomy itself has

a very high mortality rate; the second, that even if a prostate showing malignant changes be enucleated the patient runs a very considerable risk of a recurrence at some future date.

In balancing risks, therefore, it is necessary to remember that the diminished likelihood of future malignant trouble may in certain cases be more than neutralized by the immediate risk of prostatectomy. Exactly what that risk is depends on a great many factors, but at a large general London hospital I find that the mortality rate of prostatectomy for simple enlargement during the years 1914 to 1923 works out at 22 per cent. This is undoubtedly high when compared with the figures given by genito-urinary experts, but even the more favourable figures show that the death rate is above 5 per cent. It is therefore impossible to lose sight of the fact that prostatectomy must even nowadays be considered a dangerous operation. It is still more difficult to estimate the amount of protection from future malignant trouble afforded by total removal of the gland, but in this connexion it is interesting to note that of the five clinically innocent but pathologically malignant prostates recently removed by R. H. J. Swan two recurred in spite of the complete prostatectomy. It would therefore seem probable that too much emphasis has been laid on the argument that it is wise to remove all enlarged prostates simply on account of the risk of their being malignant, and, that being so, it is illogical to condemn offhand all partial prostatectomies. Since failure to obtain satisfactory results from partial operations is generally due to faulty selection of cases, it is important to consider what forms of prostatic obstruction are suitable for such treatment. First amongst these suitable cases is that which is generally known as the prostatic bar.

#### Prostatic Bars.

It has long been recognized that there are patients who have all the symptoms commonly associated with prostatic obstruction and yet in whom rectal and even cystoscopic examination fails to reveal any enlargement. This condition has been termed variously, sclerosis of the internal sphincter, contracture of the vesical neck, or, in French, "prostatisme sans prostate," but the mechanism underlying the obstruction is the same. The symptoms resemble closely those due to prostatic enlargement—namely, frequency and urgency in micturition, difficulty or delay in starting, gressive diminution in the force and calibre of the stream, and an increasing amount of residual urine, but not infrequently these begin earlier in life than is usual with general enlargement of the prostate.

The diagnosis rests chiefly on an examination of the posterior urethra and vesical neck, the cause of the trouble being found in a bar formation which affects either the posterior vesical lip or the floor of the prostatic urethra, and by its presence obstructs the outflow of urine. Our knowledge of this form of prostatic obstruction has been considerably added to by the work of Alexander Randall, who, in a series of 300

FIG. 1. — Sagittal section through a prostate showing a common type of fibrous bar, with thickening of the posterior lip, increase in the distance between the vesical orifice and the verumontanum, and a diminution in the distance between the orifice and the verumontanum. The dotted line marks off the area removed by operation.

sagittal section there is a diminution in the distance between the vesical orifice and the verumontanum, and an increase in that between the vesical lip and the perivesical tissue. It is undoubtedly due to an increase in fibrous tissue following some old-standing inflammatory process such as a chronic prostatitis. The second type described by Randall is similar to the first, except for the fact that the bar projects upwards so as to encroach

on the trigone rather than forwards towards the prostatic urethra. In the third and fourth types the bar is glandular, being due to hypertrophy of the submucous glands of the posterior commissure in the one case, and of the glands of Albarran in the other. In none of these cases is the enlargement of the bladder, trabeculation, etc., as associated conditions shows that a definite degree of obstruction exists.

However, it may be urged that even if prostatic bars of this nature exist they are so rare that, from the point of view of the practical surgeon, their importance is negligible. I cannot agree with this criticism. It has been my experience that the more careful the preliminary investigation of patients presenting themselves for prostatic obstruction, the more important does this type of case appear. How frequently has one seen a bladder opened in the expectation that a prostate suitable for enucleation would be found, and in place of this a small fibrous gland discovered which could only be removed piecemeal by scissors and forceps! Most surgeons have memories of struggles with the "small fibrous type of prostate," and not a few of their patients have been returned to bed unrelieved of their obstruction. It is difficult to find figures that will give an accurate idea of the commonness of such cases, but probably the most comprehensive are those obtained from Randall's post-mortem investigation. Out of 158 subjects showing prostatic abnormalities after death, 33.5 per cent. were examples of bar formation. As Randall's findings are very instructive in showing the relative frequency of other forms of prostatic enlargement his figures are appended:

Relative Frequency of Various Forms of Prostatic Enlargement (Randall).

800 Necropsies.	158 Prostatic Abnormalities.	
	Number.	Per cent.
Lateral lobe hypertrophies alone ...	42	26.7
Median lobe hypertrophies alone ...	22	14.0
General trilobar hypertrophies ...	3	1.9
Anterior lobe ...	8	5.0
Carcinoma ...	1	0.6
Sarcoma ...	8	5.0
Median bar—fibrous ...	13	8.2
Median bar—glandular ...	18	11.4
" " not classified ...	14	8.9
" " small and non-obstructive ...	158	

But the proof that bar formations are of frequent occurrence does not rest on post-mortem findings alone. J. R. Caulk, who has made a special study of this condition, reported in 1921 that of the cases consulting him for obstructive symptoms, 20 per cent. were examples of bars, and since that time, with a better understanding of the condition and improved methods of examination, he has found a considerably higher rate of incidence. My own observations, so far as they go, are in harmony with Caulk's.

#### Young's Punch Operation.

In 1909 H. H. Young devised an endoscopic tube by means of which prostatic bars could be removed through the urethra under local anaesthesia. Although the early instrument was in the form of a urethroscope, it was soon found that the operation of punching out an obstructing bar could be carried out efficiently without visual observation, and the original apparatus was abandoned in favour of one of simpler design (Fig. 2), consisting of an outer sheath with a window and an inner tube with a sharp cutting edge. It is employed as follows.

The bladder is distended with fluid and the instrument introduced with the inner tube pushed home so as to close the opening in the sheath. The instrument is then withdrawn with the opening uncovered so that on reaching the urethra it engages the prostatic bar, an event that is signalled by the sudden stoppage of the fluid escaping from the bladder. The operator then pushes home the inner cutting tube and excises a small fragment of

tissue. As a rule more than one cut is necessary, the foregoing proceeding being repeated, and two or three fragments removed in turn.

Since the introduction of this instrument various modifications have been made by different workers. The chief criticism levelled at Young's punch operation has been that it is liable to be followed by haemorrhage. However, although this is usually fairly brisk for a short time after operation, it does not often occasion any real anxiety. Personally I have not encountered difficulties in this direction, and my reason for abandoning Young's operation in favour of other procedures is that I have been dissatisfied with the small amount of tissue that can be conveniently removed by this method.

#### *The Cautery Punch.*

Four years ago J. R. Caulk introduced a punch in which the inner cutting tube acted at the same time as an electro-cautery, thereby reducing the risk of haemorrhage and increasing the amount of tissue removed by the operation.

In his instrument the cutting is done by a circular platinum knife, carefully insulated from the rest of the instrument and heated to a dull red heat by a suitable electric current. It has been found unnecessary to provide water cooling for the outer tube since the whole of the burning operation can be carried out within the space of five or six seconds, and very little general heating occurs. In dividing the bar the inner tube is given a rotary motion, and should it be considered advisable to increase the action of the cautery the tissue may be resected by pulling backwards the blade at half heat.

It is of the greatest importance in using Caulk's instrument to employ the right form of current, and reliable results can only be obtained by using an alternating current of about 10 volts and 150 amperes. This unfortunately limits the utility of the instrument, for the current available in different localities varies considerably, and will have to be modified in certain cases by the use of cumbersome and costly transformers. At any rate, after having made various efforts to overcome these electrical difficulties in London, I came to the conclusion that they constituted a serious objection to what was otherwise an excellent weapon, and I discarded Caulk's cautery punch in favour of the instrument described in the next paragraph.

#### *The Diathermy Punch.*

The instrument described below has been constructed for me by Mr. Schranz of the Genito-Urinary Manufacturing Company, to whose ingenuity in design I give full credit.

In external form it resembles the Young punch, but the sheath is constructed of bakelite—an excellent insulating material allied to vulcanite—with a metallic lining. This lining only comes to the surface at the edge of the window situated below the beak; elsewhere it is insulated from the urethra by the bakelite covering. (See Fig. 2.)

FIG. 2.—(1) Sheath with attachments—apparatus; (2) diathermy inlet and outlet tubes; (3) obturator; (4) punch.

into a posterior urethroscope of the Guérin type. Under guidance of the eye the punch is now withdrawn until the beak is seen to engage the window. Once it is in position the instrument is held firmly and pressure exerted on the bar by slightly raising the proximal end. Connection is then made with the source of diathermy current. Immediately the current is turned on the inner metallic layer of the sheath becomes a urethral electrode, but owing to the insulation conferred by the bakelite covering the only point of contact with the urethra is the edge of the window engaging the bar. From this edge can be observed to spread a line of coagulation which within ten or fifteen seconds whitens the whole area of prostate engaged. By maintaining continuous irrigation the process of diathermy can be carried out under complete ocular control, the current being turned

off when it is judged that a sufficient depth of tissue has been destroyed.

In order to remove the wedge of destroyed tissue and thus obtain immediate benefit without waiting for the separation of sloughs, the telescope and lighting system is withdrawn and an inner tube, resembling that used in the Young punch, inserted. By pushing this home and giving it at the same time a slight rotatory movement, a core of destroyed tissue about 2 cm. in length and 0.5 cm. in diameter may be removed. This does not, however, constitute the whole amount of prostatic tissue destroyed by the operation, the full benefit of which will only be obtained at a later period when the sloughs have separated. The telescope and lighting system may then be reintroduced, the area of operation inspected, and a decision arrived at as to whether any further fulguration is required. If the operator is satisfied with the amount of tissue dealt with, the bladder is emptied, the obturator inserted, and the instrument withdrawn.

It is obvious that the diathermy punch briefly described above offers many advantages over both Hampton Young's and J. R. Caulk's instruments, the chief of these being the avoidance of all possibility of haemorrhage by the use of diathermy, and the fact that the whole operation is conducted from beginning to end under the guidance of the eye. The use of the inner punching tube gives the same immediate advantages conferred by Young's instrument, and besides this there is the diathermy action, which adds so much to the efficacy of the operation, and which is absent in Young's procedure. It is, indeed, not unusual for a patient with complete retention to empty his bladder a few hours after treatment with the diathermy punch and for his stream to improve still further with the subsequent separation of sloughs. Minor improvements are still being made in the instrument.

#### *Fulguration of the Prostate.*

As an alternative to the punch operation prostatic bars may be dealt with through a posterior urethroscope carrying a diathermy electrode. This form of treatment has been championed in France by Luys, and in suitable cases gives good results. In England the method has on the whole been neglected, and for this reason no apology will be offered for dealing with it at some length.

Any good operating posterior urethroscope may be used for the purpose of fulguration. My own practice is to employ two instruments—a direct-vision endoscope of the Guérin or Joly type and the new prismatic operating cysto-urethroscope made by Wolfe. With the former I map out my field of operation, since it gives a clearer idea of the topography of the posterior urethra and of the mechanics of the obstruction than does the prismatic instrument. Having achieved this, I discard the direct-view urethroscope in favour of the Wolfe cysto-urethroscope, which has the great advantage of permitting the use of a larger electrode (No. 8) than the Guérin instrument, and of thus shortening the time consumed by the operation.

A current of from 500 to 2,000 milliamperes is used, and throughout the whole operation a copious stream of fluid is kept circulating through the instrument in order that a clear field of vision may be maintained. The position of the patient, the general arrangements of the theatre, and the preliminary stages of the operation are the same as for a cystoscopy. A general anaesthetic is as a rule required, but in certain cases where this has been inadvisable I have operated under local anaesthesia, the prostate being infiltrated with novocain through a needle mounted on the end of a urethric catheter. In any case, once the instrument has been introduced and fulguration started only light anaesthesia will be required. Special arrangements must be made to allow of continuous irrigation throughout the operation, and for this purpose a large-sized irrigator should be used and kept filled. In those cases in which a preliminary suprapubic drainage has been carried out there is, of course, no danger of overdistension of the bladder, and all that is necessary is to attach a length of rubber tubing by means of a glass connecting piece to the suprapubic operating table. In all other cases, however, the operator will have to keep an eye on the condition of the bladder throughout the operation, and at intervals evacuate.

FIG. 3.—Fulguration in a case of obstruction due to bar formation. In addition to the bar there exists a minor degree of enlargement of the right lobe.

It is usually more convenient to start fulguration at the bladder neck and to work towards the urethra. The method

is the same as in dealing with bladder growths, and the chief difficulties likely to be encountered are those associated with keeping a clear field and with recognizing the exact position of the operating electrode. Obscuring of the visual field may be due to blood, debris from the destroyed tissue, and bubbles of hydrogen given off at the electrode. The first two obstacles to clear vision are removed by irrigation, and the third by rotating the instrument so that the bubbles may escape to the upper part of the field. The time required to complete the operation depends on the amount of prostate requiring removal, the strength of current, and the calibre of the electrode; it may be as much as an hour where a large amount of tissue has to be dealt with. In the simplest type of prostatic bar all that is necessary is to cut a channel through the ridge so that the level of the bladder neck is flush with that of the urethra, and to widen and deepen the channel sufficiently to provide a free exit for the urine. When some lateral enlargement is associated with the bar formation it will be necessary to deal with this as well (see Fig. 3). As in the case of the bar, the portion of the lateral lobes nearest the bladder should be attacked first, the optical end of the instrument being raised so that the electrode lies in the lower part of the cleft between the enlarged lateral lobes. Energetic treatment of the adenomatous masses will be necessary if the result is to be satisfactory. Both sides should be attacked at the same sitting, each portion of the obstructing lobes being brought in turn under treatment from the level of the bladder neck outwards towards the verumontanum. Where more than a slight degree of enlargement exists several sittings may be required.

Very little after-treatment is necessary, and it is not my practice to tie in a catheter. A most remarkable point is the complete absence of pain or haemorrhage, or indeed of any other complication, after this operation. What little bleeding there is at this early period is usually due to the trauma of instrumentation, and ceases within a few hours. Most patients are able to get up and, if necessary, to leave hospital or nursing home the day following the operation, and their discomfort is certainly not greater than that commonly experienced after a cystoscopy. An alteration in the stream is not usually noted for four or six days, but as sloughs begin to come away an improvement occurs. The separation of these sloughs may be encouraged by posterior irrigation according to Janet's method. In those cases in which more than one sitting is required an interval of three to four weeks should be allowed between operations so as to allow time for the separation of the sloughs and the subsidence of the reaction. The procedure at the second or third operation is exactly similar to that of the first, and as a rule it will be found that the work is considerably easier than on the previous occasions. In the majority of my own cases two sittings have been sufficient.

#### SUMMARY AND CONCLUSIONS.

It has already been stated that the methods of treatment described in this paper are only to be regarded as a substitute for prostatectomy in certain types of case, and that diathermy or punch operations, used indiscriminately, are bound to lead to disappointment and failure. The type of case for which these methods are eminently suitable is the prostatic bar, but fulguration may also be used against the lesser degrees of glandular enlargement when for one reason or another prostatectomy is difficult or dangerous. If, however, the prostate be considerably enlarged the results obtained will in all probability be incomplete and transitory. Fulguration may also be employed, but with less certainty of success, in cases of post-operative obstruction, and in cases of malignant disease of the hard sclerotic kind.

For the sake of convenience the conclusions reached in the foregoing paper will be tabulated as follows:

1. Total prostatectomy, in spite of a fall in mortality, must still be regarded as a serious operation and one that in many cases is attended with very considerable risks.
2. The arguments for removing all enlarged prostates as a precautionary measure against malignant disease are not entirely sound, since enucleation of a gland showing malignant changes is no guarantee against recurrence, and

the immediate risk of a prostatectomy may in some cases be greater than the remote risk of malignancy.

3. Treatment by punch operations and by fulguration is of the greatest use in certain types of obstruction. These procedures are particularly suited to cases of prostatic bar, and of minor enlargement where enucleation, owing to the existence of complications, would be difficult or dangerous.

4. Success in the use of these minor operations depends on the exercise of a nice discrimination in the selection of cases. For this reason the very greatest care and thoroughness must be employed in the preliminary investigation. Otherwise the results will be uncertain and short-lived.

## THE SURGICAL TREATMENT OF CHRONIC ULCERATIVE COLITIS.

BY

SIR THOMAS CAREY EVANS, M.C., F.R.C.S., F.M.S.,  
SURGEON TO THE HOSPITAL FOR TROPICAL DISEASES, LONDON.

THE medical treatment of chronic ulcerative colitis has, in my experience, proved extremely unsatisfactory. The ordinary intestinal antiseptics by the mouth are practically useless, and the great difficulty is to determine when active surgical interference should be decided upon. There is no hard and fast line in determining when cases of colitis reach the chronic stage.

There is no doubt that a large percentage of Indian troops are "carriers" of dysentery, especially of the amoebic form; in peace, when they are comfortably housed in cantonments where they have their normal rations and are not exposed to hardships and fatigues, they suffer little or no inconvenience. The same men under field service conditions, when their rations vary in quality and quantity, usually for the worse, and especially when they are exposed to cold and wet weather, soon manifest symptoms of colitis.

My own experience of these cases has been gained under field service conditions on the north-east frontier of India, 1911-13, and in Mesopotamia during the recent war. During the operations on the north-east frontier post-mortem examinations in cases of colitis revealed the intense and extensive ulceration of the large intestine which can occur; the conditions impressed me with the utter hopelessness of medical treatment. It must be remembered that Indian troops are far more susceptible to scurvy than European troops; in my experience of active service, it takes about three months from the beginning of a campaign for the disease to show itself. The presence of scurvy or of a tendency to it is a very serious complication in cases of colitis and seriously aggravates the condition.

During the recent war (1914-18), while acting as surgeon to an improvised hospital for Turkish prisoners in Mesopotamia, and later as civil surgeon of Baghdad, an opportunity arose of observing a large number of cases of colitis; the majority were chronic and were complicated by scurvy. The combination of these two diseases made the colitis extremely intractable, and in consequence large numbers died.

While in Mesopotamia I performed appendicostomy for intractable ulcerative colitis in ten patients—Turks, Arabs, and Indians. They were all extreme cases, and all were complicated with scurvy in its various stages. The operations were performed under chloroform, and owing to the emaciated condition of the subjects the appendix was easily and rapidly approached in all cases. In the first two cases the appendix was not opened for two days, but in the remaining eight it was opened at the time of the operation, and lavage carried out at the same time, the wound being sealed with collodion. After a few irrigations of the large intestine the patients began to show remarkable improvement. The cachectic appearance due to the intestinal auto-intoxication disappeared and the general condition improved

beyond all expectations. All these cases were operated upon under very adverse conditions; there were no nurses or trained attendants to help, and there was great difficulty in obtaining fresh food and milk.

The immediate results were excellent, but it became obvious that lavage had to be persisted in for prolonged periods to maintain these results, and great care had to be taken with regard to diet. Any indiscretion in diet brought on a recurrence of the symptoms. In practically all cases ensoi was used until the washings were clean, and then ordinary saline solution. The main factor was the quantity used, several pints at each lavage being essential. I found that the introduction of a rectal tube for the evacuations was a great relief to the patient.

I regret that I am unable to give the after-history of these patients as they were transferred to other hospitals, and in those days, owing to the scarcity of medical staff, no accurate records could be kept. The immediate results in all cases were excellent, and this method of treatment impressed me as being the only rational procedure. Later on I had an opportunity, while surgeon to the Bowring Hospital, Bangalore, of observing and treating a case in more advantageous circumstances.

Nallandi, aged 34, was admitted to hospital on June 26th, 1920, suffering from chronic dysentery. He had had an attack of dysentery in February, 1920, from which he recovered; in April, 1920, he was operated upon for haemorrhoids at another hospital.

**Condition on Admission.**—He was extremely emaciated and anaemic, with sunken abdominal walls. There was extreme tenderness over the left iliac region. The liver and spleen were normal in size. The motions numbered about fifty daily; they consisted of blood-stained mucus and little faecal material. Microscopical examination showed *Entamoeba histolytica* and cysts to be present.

On June 28th an ipecacuanha bolus was divided into two parts—one was given at 5 a.m. and the other at 2 p.m., preceded by an opium draught. Stools during the twenty-four hours numbered thirty-five. The next day emetine, grain 1/2 bis in die, was given, and the stools became less frequent and less bloody.

On July 1st the patient was examined, under chloroform, with two large ulcers, oval in shape with well defined edges, the bases covered with mucus; the intervening mucous surface was reddish and granular in appearance and was covered with mucus. The emetine injections were continued up to July 6th. By this time the stools were less frequent, but the general condition of the patient was much worse.

On July 7th he was operated upon with a view of doing an appendicostomy. The appendix was found to be atrophied and useless for this purpose, so a valvular caecostomy was done, a No. 12 rubber catheter being introduced and the bowel washed out with saline solution at the conclusion of the operation.

On July 12th the patient was doing well: the stools numbered two daily; there was no blood or mucus; temperature normal. On July 19th the general condition began to improve, the septic appearance vanishing and diet being gradually increased with solids—oatmeal and biscuits. Injections of emetine, grain 1, were commenced on July 30th and given for five days as a precaution. The bowel was washed out twice daily.

By this time the patient was practically on a full diet. Three days after the irrigation ceased the fistula was almost closed, and the patient was discharged cured on December 28th, 1920, having increased over 2 st. in weight. A final sigmoidoscopic examination showed all the ulcers healed.

#### CONCLUSIONS.

Cases of colitis persisting over two or three months without intermission and with profound emaciation and anaemia which do not respond to medical treatment should be handed over to the surgeon. When they reach this stage they are invariably examples of mixed infection, whatever the organism that caused the primary infection may have been. In severe cases the large intestine may be likened to an abscess or bag of pus.

In all chronic cases a sigmoidoscopic examination should be made. In the case recorded above sigmoidoscopic examination showed the existence of extensive ulceration of the lower bowel and confirmed the diagnosis of chronic ulcerative colitis.

The only rational treatment, when the diagnosis is confirmed, is frequent irrigation of the large intestine, either through an appendicostomy or a valvular caecostomy, with ensoi solution until the washings are clean; after that, with large quantities of warm saline for prolonged periods. Valvular caecostomy is particularly mentioned, as the closing of an ordinary caecostomy may be difficult later, besides being unpleasant for the patient and for those associated with him.

## ENTAMOEBAE AS AN ETIOLOGICAL FACTOR IN MULTIPLE ABSCESES.

CLIVE J. H. SHARP, M.C., M.B., B.S.LOND.,  
D.T.M. AND H.,  
AND  
HENRY MORRISON, M.A., M.D. CANAD.,  
WEST AFRICAN MEDICAL SERVICE.

MULTIPLE deep abscesses are of frequent occurrence in Nigeria. There are two main clinical types: (a) those which affect the muscles of the limbs, and (b) those which affect the ilio-psoas muscle in particular; this type is usually single.

Although infection with *Filaria bancrofti*, *Dracunculus medinensis*, and pyogenic organisms may explain the minority, the etiology of the majority remains a problem.

Entamoebae are frequently the causative factor in hepatic abscess; they have also been reported as occurring in abscesses of the jaw, the brain, the spleen, and salivary glands. Still more recently in Captain S. Smith<sup>1</sup> has recorded their appearance in the left knee-joint; the patient in whom this occurred was given emetine and made an uninterrupted recovery.

We would suggest that in view of the various organs of the body in which entamoebae have been found, there is reason to believe that amoebic pyaemia is more than a possibility.

Jouah, an African male aged 26, cook in a European household, was admitted into hospital on May 26th, 1924, with a history of fever and pains which had lasted for three days. He looked extremely ill; the eyes were sunken and the tongue furred. On admission the temperature was 104° and the pulse 100. He had no history of diarrhoea or dysentery, and stated that there had been no dysentery among the other boys in the household.

The temperature for the first two weeks after admission fluctuated between 100° and 104°. On May 31st a swelling in the left arm was opened and pus evacuated. Following this there were remissions of the temperature to normal, but it still rose to 104° in the evenings. On June 11th three more abscesses were opened—one in the right upper arm, one in the right thigh, one in the left buttock. The temperature remained high until June 30th, when a large abscess in the muscles of the back was opened. Entamoebae were present in this pus, and 8 grains of emetine were given in daily doses of 1 grain—commencing on July 2nd. On July 1st the temperature was normal, and so remained until July 9th, when the final dose of emetine was given. On the evening of this day it rose to 101°, and again to this level on July 15th. All the abscesses healed rapidly, and there is now (July 21st) only a very little watery discharge from the wound in the back.

#### Pathological Report.

On June 30th the following facts were recorded:  
**Examination of Urine.**—Nothing pathological detected.

**Examination of Faeces.**—The ova of *Ascaris lumbricoides* were present in small numbers. No ova of *Ancylostoma duodenale* were seen. No cysts or free living amoebae were noticed.

**Examination of Blood.**—Blood smear: No parasites found. Blood count: Red corpuscles 2,244,000 per cubic millimetre, white corpuscles 4,375 per cubic millimetre. Differential count: Polymorphonuclear 54 per cent., eosinophil 5 per cent., lymphocyte 34 per cent., large mononuclear 7 per cent.

**Examination of Pus.**—This was collected in the operating theatre under aseptic conditions during the incision of the abscess situated in the muscles of the back. The following points were noted: (a) The pus contained more red cells than one was led to expect from a macroscopic examination; (b) a large number of phagocytic leucocytes and endothelial cells of considerable size were seen; (c) the pus was sterile; but (d) entamoebae were seen. The pus from the same abscess was again examined on July 2nd and was found to show the same characters as on the previous occasion. Fresh pus was on this occasion examined in warm normal saline and also in warm Weigert's iodine, and the following facts were noted: Entamoebae were present; they showed active amoeboid movements, but less active than those exhibited by similar entamoebae in faeces; they were definitely phagocytic and were seen to ingest red corpuscles as well as pus cells. There was a distinct differentiation between the ectoplasm and the endoplasm. The endoplasm was vacuolated and contained in some instances six red cells. In the iodine preparation a distinct nucleus could be seen. Stained preparations showed the same histological characteristics. On July 3rd entamoebae were again found. On this occasion the pus was taken from another abscess located in the right upper arm. Entamoebae were again found in the pus on July 4th.

The serious illness of the patient, the condition of the blood, the physical peculiarities and the sterility of the pus,

the rapidity of the healing of the abscesses, point to a peculiar cause.

The presence of amoebae in sterile pus suggests: (1) That amoebae may play an important part in the production of deep abscesses found in this country. (2) That the pus from such abscesses should as a routine be examined for protozoa, with a view to establishing a causal relationship should such exist.

This case is published by the courtesy of Mr. W. R. Parkinson, F.R.C.S.; surgical specialist, Lagos Hospital, Nigeria.

## THE NATURAL DURATION OF CANCER.

BY

S. WYARD, M.D., M.R.C.P.,

ASSISTANT PHYSICIAN TO THE CANCER HOSPITAL.

In August, 1924, Lazarus-Barlow and Leeming<sup>1</sup> published statistics of the natural duration of cancer, based upon the experience of the Middlesex Hospital. They stated that similar data were being obtained from other hospitals, and the following are the results of an examination of the records of the Cancer Hospital for the years 1900-24. The figures in the two series agree very closely, and it would appear, therefore, that they are in all probability approximately accurate. What deviation there may be from the true value cannot be estimated on account of two errors which, of necessity, enter into the calculation. First, in all cases there is a latent period, of unknown duration and certainly varying from case to case within very wide limits, wherein the developing cancer produces neither symptoms nor signs. Secondly, the date of onset is that stated by the patient, whose memory is not always reliable and observation not always accurate. The former will entail an under-estimate of the cancer's duration; the latter may introduce an error in either direction.

The cases dealt with in this paper include only a few sites—namely, rectum, breast, cervix, oesophagus, larynx, thyroid, and neck. The numbers of the first four are sufficient to make them of some value in themselves; those of the last three cannot do so, but may be of service if correlated with the figures from other institutions. In every case the duration is estimated from the reputed date of onset, and in most cases to the known date of death, but in a few instances where the patient left the hospital the length of life after discharge has been estimated by a careful consideration of the general condition of the patient and the extent of the disease when last seen, and I am convinced that no material error is introduced in this way.

None of the cases included received any but palliative treatment, which, as regards the rectum, includes colostomy. The impression gained by watching cases of rectal cancer in which colostomy has been performed is that the operation definitely prolongs life; if this were so the figures in Table II would contain an error accordingly. But when an attempt is made to estimate the increase of life no such increase is discovered (Table I).

is so extremely difficult as to give rise, probably, to great error; because it is commonly treated by gastro-enterostomy, which again in a considerable proportion of cases materially prolongs the life of the patient; and because no great number of such patients actually die in the hospital. Carcinoma of any particular site other than those mentioned

is relatively infrequent, and the numbers available for analysis so small as not to repay the labour of extraction. The duration of mammary cancer is markedly longer than that of any other cancer, while that of rectal cancer comes easily second. It is interesting to note that in carcinoma of the cervix radium treatment seems to prolong life by an average of six months, thus confirming the general opinion amongst surgeons that it is of service in these cases. Only five cases of cancer of the breast were treated by x rays the duration of twenty-four months (against thirty-nine months for untreated cases), and each of the age periods showed a corresponding deficit.

The section of the table which deals with the thyroid gland contains, it will be noticed, bracketed figures; these include one case the duration of which was stated to be thirty years. The patient eventually died in the Cancer Hospital and the malignant nature of the growth was proved, but I find it difficult to believe that it was originally malignant, and consider it probable that malignant change ensued in a previously innocent tumour. The excess of twenty in the total cases of cancer of the cervix over the combined totals treated by palliative measures and by radium is due to the fact that the former combined x-ray and radium treatment.

Although the figures given by Lazarus-Barlow and Leeming lend support to the idea that cancer is more malignant in younger than in older persons, my figures afford no confirmation for such an opinion, and the duration of life appears fairly uniform throughout all the age periods. For those sites which may be affected in either sex my figures give little, if any, indication that the duration of life is greater in females than in males.

TABLE III.—*Oesophagus, Larynx, Thyroid, Rectum.*

	Males.		Females.	
	No. of Cases.	Duration in Months.	No. of Cases.	Duration in Months.
Oesophagus	171	9	36	12
Larynx	44	14	8	14
Thyroid	4	17	9	8*
Rectum	256	28	191	29

\* If the case mentioned in the text, and said to have had a duration of thirty years, be included, this figure becomes 45. There was no case in the series of malignant cervical glands in a female.

In conclusion, my thanks are due to Miss Hower of the Cancer Hospital, by whom was performed the labour of searching the hospital records and abstracting the notes of over 2,000 cases, which form the basis of these statistics.

## THE USE OF INTARVIN IN DIABETES MELLITUS.

BY

D. MURRAY LYON, M.D., W. ROBSON, Ph.D.,  
AND A. C. WHITE, M.B.  
(From the Department of Therapeutics, University of Edinburgh.)

THAT the fatty acids are broken down during oxidation by the removal of two terminal carbon atoms at a time ( $\beta$ -oxidation) seems to be fairly well established. Knoop in 1904, in his classical investigations on the fate of the phenyl fatty acids in the animal organism, was the first to propound this theory, which was ridiculed by the pure chemists until Dakin<sup>1</sup> was able to show that an analogous breakdown of these and similar substances could take place *in vitro*. The investigations here referred to were all concerned with the oxidation of fats with an even number of carbon atoms in their molecule. Höckendorf<sup>2</sup> had earlier shown that the introduction into the diabetic

organism of alcohols containing an odd number of carbon atoms, and which therefore on oxidation probably give rise to fatty acids with an uneven number of carbon atoms, brought about an increased excretion of carbon. Embden and his co-workers<sup>3</sup> found that on perfusing freshly excised liver with the lower members of the fatty acid series only those containing an even number of carbon atoms in their molecule yielded glucose in the diabetic result of their katabolism. Then Ringer and Jonas,<sup>4</sup> working with homologues of propionic acid, showed that valeric and heptylic acids yielded glucose in the diabetic organism roughly in proportion to the amount of  $\beta$ -oxidation, while butyric and caproic acids led to the increased excretion of aceto-acetic acid without increased glucose elimination. It was then that Ringer conceived the idea of looking for a suitable odd-carbon atom fat to be used in the treatment of acidosis, and which could be given in considerable amounts to diabetics without the possibility or danger of acidosis arising. His attempts, however, to synthesize such a suitable fat were unsuccessful, to writers—namely, Janeway and Mosenthal—also saw the possibilities. Max Kahn succeeded in synthesizing a suitable fat— $C_{15}H_{31}COOH$ , margaric acid—which is easily purified and which, when united with glycerol, forms a neutral fat. This compound, commercially known as intarvin, apparently can be katabolized in the organism without yielding ketogenic derivatives. Kahn states<sup>5</sup> that on administration to phlorizinized dogs this fat causes a marked increase in glucose elimination in the urine, showing that in the dog it is broken down to propionic acid and then converted into glucose in accordance with the theory brought forward by Ringer and his co-laborators. In this communication he brings forward a certain amount of data to confirm his claims of the previous year.<sup>6</sup> He recommends the use of this fat in those cases where insulin has no apparent or only a moderate effect up to the extent of 1,000 calories daily from such a source. He also gives data from a patient with diabetes complicated by tuberculosis, who was fed with intarvin. In this subject it was found that 100 grams of intarvin given in addition to the ordinary diabetic diet caused no ketonuria, and the carbon dioxide combining power of the blood increased, while the blood sugar during this time remained below the threshold value. In December, 1923, he published<sup>7</sup> a more extensive series of observations to substantiate his claim.

In his first case, one of starvation acidosis, he found that the addition of 100 grams of intarvin caused the acetone to disappear, while on replacing it the next day with an equal weight of butter the acetone returned once more, to disappear next day on administration of the same quantity of intarvin.

In his second case, showing acetoneuria and acetonæmia even on a low fat diet, the addition of 90 grams of intarvin cleared the acetoneuria, and when an aliquot portion of intarvin was given the next day the acetoneuria also went. The patient's blood sugar also came nearer to a normal level.

In the third case it was found that when the patient had been rendered ketone-free without intarvin, 150 grams of this substance could be added to his diet without ketonuria reappearing, and the bicarbonate reserve of the blood increased while the blood sugar remained normal.

In the fourth case, one of pituitary glycosuria where insulin was ineffectual, feeding with the odd-carbon fat cleared up the acetone and brought about a gain in weight and the glycosuria was controlled. When the intarvin was omitted, ketonuria and glycosuria immediately reappeared.

Joslin<sup>8</sup> also reports favourably upon this fat. He states: "It would appear to be ideal in the instance of acidosis in the presence of infection," and "It can logically be recommended to those cases with whom the fat-carbohydrate ratio is above 3:1."

French workers<sup>9</sup> have also brought forward evidence in favour of the antiketogenic function of intarvin. There are, however, certain dissentients. Serringhaus<sup>10</sup> reports that after comparing the effect of ingestion of beef suet and an equal quantity of glyceryl margarate in a ketonuria following carbohydrate starvation—

"Glyceryl margarate seems to have little or no ketolytic value aside from its glycerol content. It does not exert a protein sparing action in these diets."

Allen<sup>12</sup> condemns the use of artificial foodstuffs, including intarvin, in endeavouring to provide weight and strength for the diabetic, as for ever fruitless, being based on a superficial and false conception of the disease.

In view of this it seemed of interest to see what could be done with intarvin in cases of diabetes mellitus under treatment. Some of the relationships of intarvin to metabolism were consequently determined in four diabetic subjects, and, in addition, the effect of the absorption of intarvin on the blood fats was determined in two normal individuals.

Regarding the palatability of the fat, individual taste varies, but in our experience it was always found to be disagreeable, more especially if taken along with other food. Probably the mineral oil with which it is mixed when prepared for commerce had something to do with this. There is, however, no doubt that the intarvin is absorbed; both Kahn and Sevringhaus (*loc. cit.*) showed it to be 97 per cent. absorbed—that is, practically as well as beef suet would be under similar conditions. Considering that it was supposed to be antiketogenic in function it was thought worth while to determine whether the absorption of intarvin had any effect on the blood sugar.

#### Intarvin in Normal Subjects.

The following table shows the response of one of the normals (W. A.) to 250 c.cm. of 40 per cent. cream on a fasting stomach.

TABLE I.—Response to Ingestion of 250 c.cm. of 40 per cent. Cream. (Normal Subject.)

	Hours after Ingestion.					
	0	1	2	3½	5	6½
Total blood fat in mg. per cent. (Blood)	455	435	411	504	460	414
Blood sugar in mg. per cent. ...	97	106	97	101	111	—
Respiratory quotient ...	0.90	0.80	0.78	0.79	0.81	0.80

Figures for cholesterol (whole blood) and for the metabolic rate showed no significant change and are not recorded. The maximum rise in the blood fat occurs earlier than in the cases reported by Cowie and Hoag,<sup>13</sup> otherwise there is little to note. The intarvin absorption curve of this subject shows similar features. On one occasion the intarvin, to render it more palatable, was made up with washed bran. The blood cholesterol showed a considerable rise at the end of the first hour (accountable for by the sterol content of the bran itself). Details being more complete as regards the intarvin absorption curve of the other normal (W. R.), the results are given in Table II.

TABLE II.—Response to 100 grams of Intarvin. (Normal Subject.)

	Hours after Ingestion.					
	0	1	2	3½	5	6½
Total blood fat in mg. per cent. (Blood)	770	806	881	916	823	818
Blood sugar in mg. per cent. ...	103	125	118	114	108	125
Respiratory quotient ...	0.76	0.74	0.79	0.79	0.81	0.82

Blood cholesterol and metabolism showed no significant changes. In both cases it was found that the ingestion of the intarvin resulted at the end of the experiment in a certain looseness of the bowels, due probably to the mineral oil it contains. At no time did the respiratory quotient give any indication of the burning of carbohydrate in excess of normal. The urine in both cases did not show any abnormal constituents.

#### Intarvin in Diabetic Subjects.

In order to determine accurately the value of intarvin in diabetes it was considered desirable to have the diets of the patients stabilized at the highest possible level within the limit of tolerance, and then to add a quantity of intarvin. Patients were treated on the lines described in the BRITISH MEDICAL JOURNAL, August 23rd, 1924.<sup>14</sup> The diabetic cases were as follows:

#### CASE I.

A. R., aged 31. History of diabetes for four months. Admitted February 20th, 1924. On a diet of 1,210 calories ("B 12": carbohydrate 61.5 grams, protein 47.5 grams, fat 89 grams. G:FA::1:1) the patient excreted 41 grams of glucose in twenty-four hours. Acetone positive in the urine. The acetone and sugar were both got rid of from the urine by dieting alone, and the diet was built up to 2,400 calories. On March 12th on this diet it was found that the blood acetone (Van Slyke and Fitz) rose to 100 mg. per cent. two hours after breakfast, falling to 9 mg. per cent. two hours later, and remaining at this level for another two hours. Next day, similar conditions showed a fasting blood acetone of 5.8 mg. per cent., rising to 640 mg. two hours after a breakfast to which 100 grams of intarvin had been added, and falling to 36 mg. per cent. two hours later, to rise at the fourth hour to 42 mg. The blood fats showed a certain parallelism, but rose again at the end of the period. There was definite acetouria, 364 mg. per cent. of acetone being present in the urine passed four hours after the intarvin.

#### CASE II.

W. D., a gardener, aged 41. Duration of diabetes uncertain. An ophthalmologist diagnosed diabetes three months before admission, while the sight of the right eye had begun to fail twelve months before that. Admitted March 18th, 1924, on a diet of 1,524 calories ("B 15": carbohydrate 78 grams, protein 60 grams, fat 108 grams. G:FA::1:1). On March 19th the urine was acetone-free and the total glucose lost in twenty-four hours was 23.4 grams. The diet was gradually and with difficulty built up to 1,505 calories ("C 15": carbohydrate 50 grams, protein 49.5 grams, fat 123 grams. G:FA::1:1.6). Blood examinations were made during April 10th; these were repeated on April 11th, 100 grams of intarvin having been given in addition to the breakfast. The intarvin was continued at the rate of 100 grams per diem on the same diet until April 16th. The figures for April 17th represent the termination of the intarvin period. The specimens recorded as before 10 a.m. are fasting samples. Details of examinations in this case are given in Table III.

TABLE III.—CASE II.

\* Indicates days during which intarvin was given.

The twenty-four hour urine during the intarvin period showed a slight trace of sugar, not estimable. Cholesterol and general metabolism figures revealed nothing. During the period of intarvin administration there was a temporary rise in the fasting blood fat and a gradual rise in the blood acetone percentage, fairly well reflected in the findings for urinary acetone when compared against the fasting blood samples. The respiratory quotient showed no typical change. The faeces during the intarvin period contained 47 per cent. fat, of which 84.5 per cent. was unsplit. The large percentage of unsplit fat was probably due to the unabsorbed mineral oil portion of the intarvin.

#### CASE III.

D. B., aged 30. Duration of diabetes, fifteen months. On April 19th, 1924, the patient was put on a diet of 1,524 calories ("B 15": carbohydrate 78 grams, protein 60 grams, fat 108 grams. G:FA::1:1). The urine showed acetone, and 41.1 grams of glucose were lost in the twenty-four hours on this diet. The patient was made sugar- and acetone-free. The diet was built up to 1,896 calories ("C 19": protein 57.5 grams, fat 158 grams. G:F: diet at this level on May 20th, from May same diet was given, with, in addition, 100 grams of intarvin per diem. During this period the blood acetone was only slightly increased, and the total fats and cholesterol remained fairly steady except towards the end, when the blood fat started to rise. The cause of this cannot be explained. Later, when the patient

N.B.—In sections B and C above the figures are obtained from samples of blood taken, and of urine passed about 9 o'clock each morning while the patient was still fasting.

\* In section C 50 grams of butter fat replaced the intarvin previously given. † 100 grams olive oil added to diet of August 21st.

was put on insulin 20 units per diem, the fats rose still higher. The total urinary acetone for twenty-four hours was on May 21st 0.35 gram, and on May 28th 1.35 grams. There was a faint indeterminate trace of lower sugar per twenty-four hours during most of the intarvin period. During the whole of the period the fasting blood sugar was below the normal threshold value. Thus, while the evidence obtainable for blood acetone was doubtful, we found that the total acetone excretion had risen. As in Case II, the faeces showed a high percentage of unsplit fat during intarvin administration, probably for the same reason.

#### CASE IV.

D. R., aged 55. Diabetic discovered four years previously during examination for life insurance. Apparently the disease had always been of the mild type. The patient was admitted on July 10th, 1924. After a test meal of 50 grams of glucose the blood sugar rose to 200 mg. per cent. at the end of the first hour, but had returned to normal at the end of three hours. In this subject the intarvin was administered in two different periods: (a) in the pre-stabilization period as the diet was being built up (July 16th and 17th); (b) from August 6th, when the diet was in a more stable condition. During the first period it was found that the addition of intarvin to the diet was associated with increase of acetone.

The diet was then built up without intarvin (to "C 25"—that is, 2,500 calories per diem), but to make sure that even with intarvin the diet would still be within the patient's tolerance it was kept 100 calories lower during the experiment—that is, 100 grams of intarvin were added to a diet containing 2,400 calories from August 6th to 12th. August 10th, however, was made a low day, with only 952 calories besides the 100 grams of intarvin, and the diet on August 11th and 12th was kept at 2,300 calories along with the intarvin. With the exception of the first day, the twenty-four hours sample of urine showed an indeterminate trace of sugar throughout the whole period. This disappeared on stopping the intarvin. The diet was kept at 2,300 calories per diem during August 14th and 15th, and 50 grams of butter fat were added each day. On August 21st 100 grams of olive oil were given along with ordinary diet, and acetoneuria was definitely produced.

It will be noticed that, even during the stabilized period, intarvin when added to the diet tended to increase the percentage of acetone in the blood and also the total excretion of acetone, especially towards the end of the period.

This, in view of its supposed antiketogenic function, is rather disappointing. The increase, however, is not so marked as when ordinary fat is given—for example, the figures of August 14th and 15th, when 50 grams of fat were given to replace the intarvin. When 100 grams of olive oil were taken on August 21st there is again a much greater increase in the total acetone lost.

#### Discussion.

From the above observations on the use of intarvin in diabetes it would seem that further investigations are needed into the whole question before the claims on behalf of this fat can be fully substantiated. In the cases recorded no reduction, but rather an increase, in the amount of acetone in the blood followed the administration of intarvin. The rise, however, is less than when an equivalent quantity of other fat is added to the diet. The average G: FA ratio in the diets employed was 1 to 1.5, so that there was ample carbohydrate to burn up the ordinary fat of the diet, apart from the intarvin. The respiratory quotient did not at any time give indication of more carbohydrate than usual being burned under the influence of intarvin, as might be expected if the acid ultimately broke up to form sugar. On the other hand, the addition of intarvin to a stabilized diet always led to the excretion of small traces of sugar in the urine. The changes in the blood fat under intarvin are simply recorded. These cannot be explained as yet. Further investigation of this question is in progress. When a patient's diet has been stabilized at his maximum tolerance, 100 grams of intarvin can be added (allowing about 700 extra calories) without the appearance of clinical signs of acidosis. But, in view of the conflicting figures obtained regarding the control of ketosis consequent on its use, intarvin cannot be used indiscriminately to build up diets to a maintenance level without fear of ketosis. The expense

and the unpalatability of the substance will also militate against its general acceptance in practical dietetics.

## THE PERMEABILITY OF MENINGES TO URANIN AS A METHOD IN THE DIAGNOSIS OF MENINGITIS.

(Preliminary Communication.)

BY

OTTO JERVELL, M.D.

(From the Christiania (Oslo) Municipal Hospital,  
Medical Section VIII.)

A METHOD whereby it is possible to decide simply by lumbar puncture whether meningitis is present or not may possibly be of interest. The normal meninges and plexus choroides have the power of preventing a number of substances that are foreign to the organism from passing into the spinal fluid; diseased meninges have lost this power. Especially in meningitis this permeability of the meninges to chemical substances is greatly increased, and it is thus natural to investigate whether the determination of the latter can be of assistance in diagnostic difficulties. The substance must be easily found in the spinal fluid and be non-poisonous. Such a substance is uranin (sodium fluorescein), a red colouring matter very readily soluble in water; a weak solution gives an intensely light-greenish fluorescence which strongly recalls the fluorescence seen in a positive Schlesinger reaction. The fluorescence does not disappear until the solution is weakened to 1 in 10,000,000. Weaker solutions have a dirty greenish colour, without fluorescence.

A series of investigations carried out by Kafka,<sup>1</sup> Schönfeld,<sup>2</sup> Jørgensen,<sup>3</sup> and others have established that uranin, in doses of 6 to 8 grams by the mouth, passes into the spinal fluid in about 30 per cent. of healthy individuals, but in small quantities only. In dementia paralytica, and also in syphilitic persons, uranin was found more frequently in the spinal fluid, especially if it was altered. These authors do not appear to have made any determination of the permeability of the meninges in meningitis.

Uranin given in larger doses enters the spinal fluid where the meninges are not infected, and the patient's skin becomes intensely yellow. After several experiments we decided upon 2 grams of uranin for an adult, or about 0.03 per kilogram of body weight. One or two hours after such a dose the patient turns yellow, but the coloration is not stronger than in icterus, and the yellow colour of the skin and mucous membrane disappears comparatively quickly, as a rule after five to six hours. Uranin has no poisonous effects, and according to C. Jørgensen's investigations does not irritate the meninges. It can be administered by the mouth or by intramuscular injection in a 20 per cent. solution, but not subcutaneously, as a strong solution produces a sensitive infiltrate. After half an hour to an hour the blood serum gives a greenish fluorescence, which in the great majority of cases does not disappear until the serum is weakened to 1 in 64. The concentration of uranin in the blood is strongest two to three hours after it has been given, and it is at that time, therefore, that the lumbar puncture should be performed. We employ the following technique:

The patient is given 2 grams of uranin by the mouth (preferably in wafers) or by intramuscular injection (20 per cent. solution) if he is not quite conscious. Three hours later lumbar puncture is undertaken in the usual manner. In order to ascertain whether

the spinal fluid is fluorescent or not, the test tube must be held against a dark background. In meningitis the fluid gives off a distinct greenish fluorescence. No importance should be attached to a doubtful fluorescence. The presence of blood may confuse the reaction, since the blood contains great quantities of uranin. Investigations made at this section prove, however, that at least 1/3 c.cm. of blood must be mixed with 10 c.cm. of spinal fluid in order that the latter shall become fluorescent.

We have employed this simple method with 74 patients, 18 of whom were suffering from various forms of meningitis. The spinal fluid (from, in all, 22 lumbar punctures) taken from patients suffering from meningitis was in all cases fluorescent, in some quite strongly, like a markedly positive Schlesinger reaction. It is true that the fluorescence was weak in three instances, but nevertheless distinct. The method used in these cases, however, differed somewhat from the technique usually employed, the lumbar puncture being performed within one hour after the patient had received the uranin. In addition, the dose of uranin given to two of the patients was too small (1 gram). The spinal fluid in 38 of 56 non-meningitic cases was as clear as water. In 8 cases the fluid was of a dirty green colour without fluorescence; this shows that minimum quantities of uranin had entered the spinal fluid. In 10 cases the spinal fluid was faintly fluorescent, but in 7 of these there was an admixture of blood, which, as mentioned above, makes the results uncertain. Three of the non-meningitic cases, on the other hand, exhibited a faintly fluorescent spinal fluid three hours after 2 grams of uranin. The fluorescence disappeared, however, in a dilution of 1 in 2, whilst the spinal fluid from patients with meningitis showed fluorescence in a dilution of 1 in 8 and up to 1 in 30. (For this determination we employed small test tubes 11 mm. in width, and observed the fluorescence in a dark box, where the light at a distance of 15 cm. enters through a 20 dioptic biconvex lens.)

### Conclusions.

Uranin in doses of 0.03 gram per kilo of body weight does not enter the cerebro-spinal fluid, or does so only in small quantities if the meninges are not infected. In meningitis the colouring matter enters the fluid in easily demonstrable quantities. If, therefore, by lumbar puncture three hours after uranin has been given in the doses stated, the spinal fluid shows a distinct greenish fluorescence, we can with great probability diagnose meningitis without making other investigations of the spinal fluid. If the spinal fluid shows no fluorescence, meningitis can with certainty be excluded.

It is not possible to decide what form of meningitis, if any, is present. The passing of the colouring matter into the spinal fluid merely indicates the greater or lesser permeability of the meninges. In meningitis comitans, circumscripta, etc., the uranin does not enter the fluid, or does so in relatively small quantities, even when pleocytosis is present. Opinions differ as to whether it is correct to designate these conditions meningitis, but this is doubtless chiefly a dispute about words.

## A WEAK POINT IN STERILIZING METHODS.\*

BY

KENNETH BLACK, F.R.C.S. Eng.,

PROFESSOR OF SURGERY, KING EDWARD VII COLLEGE OF MEDICINE,  
SINGAPORE.

ONE of the problems of the operating theatre is to ascertain the temperature reached in the centre of a packet, tin, or drum of dressings in a sterilizer. It is very different from that of the steam around the outer side of the packet or tin, but the latter alone is registered by a thermometer projecting into the sterilizer and capable of being read from the outside, or, more commonly, by means of a pressure gauge. I made tests with a specially prepared thermometer, similar to a clinical thermometer

\* Read at a meeting of the Malaya Branch of the British Medical Association.

but registering far higher temperatures. I placed it inside a tin of dressings, which I then "sterilized" in a high-pressure sterilizer of the largest and most up-to-date pattern. When the temperature of the steam in the inner jacket of the sterilizer was  $240^{\circ}$  F. that in the middle of the tin of dressings was only about  $160^{\circ}$  F. After screwing down the safety valve of the sterilizer and "sterilizing" for more than an hour after the maximum pressure had been registered by the gauge, the special thermometer in the centre of the tin registered  $220^{\circ}$  to  $230^{\circ}$  F. I tested many other sterilizers, and found that all those of low pressure, such as are used ordinarily in nursing homes and small hospitals, were practically useless, whilst even those of high pressure were mostly inefficient unless "sterilization" was continued for a far longer period and at a higher pressure than that suggested in the maker's printed instructions. On one occasion a theatre sister, doubting the accuracy of my suggestion that her high-pressure sterilizer was not efficient, took the trouble to place a raw egg in the middle of each packet of dressings, but, after completing the "sterilizing" process, discovered that the eggs were still raw. Afterwards she "sterilized" several times at a temperature and pressure regarded as dangerously high, previously having placed my special high-registering thermometer in the inside of the drums of dressings. She discovered that my thermometer even then rarely registered a temperature exceeding  $200^{\circ}$  F.

It is possible, of course, to argue that if no mischief has been proved to have resulted from the ordinary methods of "sterilization" it matters little whether or not a very high temperature has been obtained in the middle of the tin of dressings. It would be equally possible, however, to argue that, if no mischief has resulted from the use of dressings that have not been "sterilized" at all, "sterilization" is a superfluous precaution. I scarcely believe, nevertheless, that failures to detect and record mischievous results are likely to convince competent surgeons that "sterilization" by sterilizers is useless. Probably they will continue to believe that, when "cooking" our dressings, towels, overalls, etc., we ought to aim at obtaining in the inside of each drum or packet a temperature at least equal to that of the boiling point of water ( $212^{\circ}$  F.).

I have for many years past endeavoured to solve the problem of ascertaining easily and economically the temperature inside a tin of dressings undergoing "sterilization." There is no difficulty, of course, in ascertaining this temperature by means of the special thermometer already mentioned. Such a thermometer, however, is unsuitable for ordinary use, being costly, easily broken, and inconvenient. I have tried, therefore, to find an economical and convenient substitute.

On discovering that a famous surgeon had been experimenting with tiny tubes of phthalic acid, I obtained a number of these from the Paris firm that made them. I placed a tube within each of several tins of dressings, which I then proceeded to "sterilize." The powder in each tube was supposed to change colour from white to red as soon as a certain very high temperature (I think  $300^{\circ}$  F., but am not quite sure) had been reached. I found, however, by experiments, that the powder always changed colour from white to red during "sterilization" of a tin, no matter what temperature was indicated as having been reached. I found also that the powder changed colour to red when I left a tube in my waistcoat pocket for a week, or even when I held it in a warm hand for a time. Clearly, therefore, these tubes of phthalic acid do not suffice for our present purposes.

Afterwards I gave a trial to various kinds of wax. Finally, I made a series of experiments with fusible metals, and was encouraged, eventually, to devise the pyrometer here described. It is placed in the inside of a tin, drum, or packet of dressings, etc., and remains there during the process of "sterilization." It consists of a round piece of fusible metal, each having a different fusing point. Convenient fusing points have been found to be  $190^{\circ}$ ,  $200^{\circ}$ ,  $212^{\circ}$ ,  $220^{\circ}$ ,  $230^{\circ}$ , and  $240^{\circ}$  F. Each square is marked with its own fusing point, and the cardboard is similarly marked in the proper places. When the temperature of  $190^{\circ}$  F.

is reached the first square fuses; when that of  $200^{\circ}$  F. is reached the second square fuses, and so on. Consequently, by glancing at the pyrometer when the dressings are unpacked after "sterilization," the surgeon can see how many squares have fused, and consequently what minimum temperature has been reached in the inside of the packet or tin. When a square fuses its surface becomes rough and its outline blurred, whereas an unfused square remains bright and its edges sharp. As the pyrometer can only be used once cheapness is essential. A pyrometer consisting of only one thin square of fusible metal melting at exactly  $212^{\circ}$  F. would suffice, and its cost would be insignificant.

Messrs. Matthey and Johnson of Hatton Garden make these metals to melt at any temperature desired. They all contain bismuth, and this renders the metal somewhat brittle to roll into sheets, but it can be cast fairly easily into thin plates or melted into tiny square castings. The accuracy of the actual melting points is easily checked.

It has rather surprised me that none of the surgical instrument makers, apparently, has ever seriously endeavoured to provide surgeons with a cheap or reliable test of the machines they supply, which are believed and claimed to sterilize the contents of the largest drums, even when tightly packed. I noted that the standard type of dressing drum, with holes that close and open, possesses no advantage over an ordinary plain metal box with a hinged lid, which is closed over a layer of cotton-wool. The superheated steam appears to penetrate into the latter, even when closed, just as readily as into the former, and the latter has the advantage that it more nearly approaches the ideal organism-proof receptacle than the former, with its numerous loopholes for the possible entrance of bacteria.

## A DIATHERMY SNARE FOR REMOVAL OF POST-NASAL GROWTHS.

BY  
E. BROUGHTON BARNES, F.R.C.S. Ed.,  
NORTHAMPTON.

The diathermy snare here illustrated was devised by me and I have used it on an angio-fibroma of the nasopharynx with success.

The snare consists of a vulcanite body, with metal liner with solid end, into which the diathermy cable screws. In the liner of the body of the snare is a hollow metal slide. The wire, which is of hard drawn silver, is passed through the stem of the snare into this slide, and a vulcanite-headed screw works through a slot in the body into the slide and grips the wire in it. The diagram, in which the snare looks rather frail, though it actually is, shows the mechanism clearly. The instrument was made for me by Messrs. Watson (Kingsway), and the arrangement of the instrument is their design.

The case in which I used it was that of a boy of 13 with an angio-fibroma springing from the basiphoid by a pedicle half an inch broad and a quarter of an inch thick. The tumour was about 1 1/2 in. long by 1 by 3/4 in., and showed below the soft palate. The wire was passed through the mouth over the pedicle and forced against the basiphoid with the finger-nail; it was then tightened and the current was switched on at a fairly high amperage. The wire came home and the tumour fell off in about three seconds. There was no stain of blood. At no time after the operation did the child have any pain at all. Five weeks later I saw the boy and was unable to detect any sign of growth. Apart from the simplicity of the procedure and freedom from haemorrhage with the diathermy snare, it seems probable that there will be less liability to recurrence after the use of the diathermy snare than if the tumour had been removed by ordinary surgical procedures.

The only precaution is to see that the child's nasopharynx is low, as the tumour falls free, and might be aspirated into the glottis. Microscopic examination showed that the tumour in this case was very vascular.

## A TINEA X-RAY COUCH.

BY

J. GOODWIN TOMKINSON, M.D.,

PROFESSOR OF DISEASES OF THE SKIN, ANDERSON COLLEGE; PHYSICIAN,  
SKIN ELECTRICAL DEPARTMENT AND DISPENSARY SKIN PHYSICIAN,  
WESTERN INFIRMARY, GLASGOW; DERMATOLOGIST, GLASGOW  
AND COUNTY OF DUMBERTON EDUCATION AUTHORITY.

IN x-ray treatment of tinea tonsurans irradiation of the Kienböck-Adamson suboccipital area, and to a less degree

the vertical one, often gives some difficulty owing to variation in the shape of heads, and also from the risk of pressure on the nose—and consequent movement of the head—where the prone position on the couch is practised. The alternative position of sitting on a chair with forehead supported on the dorsa of the hands resting upon the couch is oftener than not accompanied by a tendency to slip down somewhat in the chair and so disturb the position of the head. To obviate these contingencies and at the same time retain the prone position, which ensures stability better than any other, I designed a couch which was made by the master of works, County of Dumbarton Education Authority, for the skin clinic, where it has been used since March 17th,

Under surface of tinea couch, showing method of operating hinged flap.

1923. It is constructed as follows. In the top of the couch is introduced a movable flap with circular aperture to accommodate the face, and so hinged as to allow of its being easily raised or lowered, at the free end, in relation to the level of the top of the couch. A screw, technically known as a "Leggott's quadrant," which is operated with a short "endless" cord, is attached at the free end of the flap. The cord passes over two small pulleys attached to the under surface of the head of the couch. The flap remains firmly fixed in the desired position when

having to wind the cord round any part of the couch; it can be altered at any moment by manipulating the cord, and is capable of the nicest adjustment. The accompanying photograph of the under surface of the top of the couch illustrates the mechanism. It will be seen that all pressure on the nose is avoided and variation in cranial shape combated by the hinge adjustment. Experience of working with it has suggested structural modifications which would to some extent increase its efficiency. One is to change the position of the flap so that its free edge would form part of the end of the couch; another is slightly to alter the shape of the

aperture, or, better still, to make it variable; these modifications I am about to introduce.

## PULMONARY EMBOLISM.

IN view of recent discussions on pulmonary embolism and thrombosis, the following case may prove of interest.

Mrs. H., aged 55, was admitted to the Christie Hospital with epithelioma of the vulva. She was treated with radium, and, ten days later, by diathermy. Her general condition, both before and after operation, was good. Her temperature was raised for three days subsequent to the operation, the maximum being 100° F., and she complained of constant pain at the site of the lesion for the first week or ten days. She felt perfectly well, but was unable to sit up, owing to the tenderness of the raw surface left after the diathermic treatment.

Three weeks after operation she was still in bed and the wound was about two-thirds healed. On the morning of the twenty-second day she complained of high epigastric pain and some dyspnoea. She was noticed to be slightly cyanosed, and the pulse and respiration rates were increased. These both rose rapidly, the cyanosis deepened, the pulse became weak and thready, and collapse supervened. Ten minutes after the onset of symptoms she lost consciousness, the breathing became stertorous, the pulse and respiration rates dropped, and death took place about five minutes later.

*Post-mortem Report* (Dr. Powell White).—The pulmonary artery contained blood clot which was mostly recent and appeared to have been formed immediately before death, but some was of earlier date; it was not adherent. The clot extended to some of the arterial branches in the upper lobes of both lungs, but not into the lower lobes. The upper lobes were partially collapsed and dry, and the lower ones were normal and moist. The right ventricle could be found. The blood in the left side of the heart, the aorta, the venae cavae, the portal and the iliac veins was quite fluid. The smaller pelvic veins, especially those coming from the uterus and vagina, were distended with blood clot. The external iliac veins on both sides were enlarged and hard.

This case was in all probability one of pulmonary embolism followed by thrombosis in the pulmonary artery; it is probable that the embolus came from one of the pelvic veins in the neighbourhood of the uterus or vagina. An illustrative factor in pulmonary embolism. The main factor here must have been the patient's enforced recumbency for three weeks; she had lain quite still all day and night, in spite of

being urged to move about as much as possible without causing herself undue pain. The circulation in the veins of the pelvis and lower limbs must have been at an extremely low ebb, especially as the force of her heart beat, though adequate, was never great. The other factor which probably played a part was sepsis. The embolus evidently arose from one of the smaller uterine or vaginal veins, there having been found at the necropsy to be distended with clot. The venous drainage of the site of the necessarily septic lesion, the perineum, is ultimately the same as that of the uterus and vagina—namely, into the internal iliac veins. It is also extremely likely that infection had spread directly from the perineum along the vagina into the parametric tissue, which contains those veins that were found to be affected.

Manchester.

## BILATERAL CYSTIC EMBRYOMA OF OVARY WITH TORSION OF THE PEDICLE OF ONE CYST.

THE following case seems to be of interest on account of the fact that a cystic embryoma existed in each ovary and that there were no definite symptoms until the torsion of the pedicle of one took place.

A married woman, aged 36, sent for me on the evening of November 13th, 1924, complaining of pain in the abdomen and difficulty in passing urine. She had been treated for floating kidneys with a Curtis belt. One child, born ten years ago, died at 4 years of age. Her periods were regular and normal.

*History of Present Condition.*

She was quite well until the morning of November 13th, when she awoke with pain in the lower part of the abdomen and difficulty in passing urine. She stated that she had had similar attacks, but had put them down to her floating kidneys. A period was then just ending.

*Condition on Examination.*

When I saw her she was sitting up in bed and leaning forward, as this position gave her relief. The temperature and pulse were normal. She was of spare build and had a goitre with some exophthalmos.

The abdomen showed slight bulging above the symphysis pubis, which on palpation gave the impression of a cystic tumour rising from the pelvis in the mid-line halfway to the umbilicus. On

pressing on the tumour she felt a desire to micturate. The right kidney was palpable and the left distinctly mobile. The uterus was retroflexed and separate from the swelling, which lay between it and the symphysis pubis, and felt like a tense full bladder. Nothing else abnormal was found in the pelvis.

There being no facilities for a hot bath, etc., I obtained the services of a nurse to pass a catheter. She reported that she withdrew only 2 drachms of urine. When I again examined the patient there was no change in the condition. I saw her the next morning, and although she had passed urine in small quantities the tumour persisted.

She was admitted to the Kingston Victoria Hospital, where she first had a hot bath. I then passed a metal catheter. The bladder was empty and the beak of the catheter could be felt in the stretched-out bladder superficial to the tumour. Ovarian cyst, probably on account of its position a cystic embryo, was diagnosed. The temperature was 99° and the pulse 76. As there appeared to be no urgency, operation was not performed until the following day, November 15th.

#### Operation.

The usual subumbilical incision was made and a greatly engorged ovarian cyst presented. This was delivered intact through the wound and found to arise in the right ovary. It had rotated on its pedicle through two complete turns. The pedicle was clamped and divided, and the stump ligatured and covered with peritoneum. The left ovary contained numerous follicular cysts and one larger one the size of a bantam's egg. The latter was incised and a creamy fluid, followed by hair, exuded. The opening was clamped and the cyst dissected out. The rest of the ovary was left, as it evidently contained a considerable amount of active ovarian tissue. The abdomen was closed in layers. The Fallopian tube was spread over the surface of the larger cyst. It was as large as a full-term foetal head. On incision a quantity of cream-like sebaceous material, with a lump of hair, escaped. The inner wall was smooth except for one spot, from which a tuft of hair was springing. The smaller cyst showed, projecting from its inner wall, a prominence the shape of a rabbit's heart, from which hair was growing. This prominence had a central cavity apparently lined with mucous membrane. A microscopic section showed a cystic embryo with great hyperplasia of the sebaceous glands. Sweat glands and hair follicles were also seen, and externally a layer of tissue resembling lung.

There is little doubt that the larger cyst used to become partly twisted on its pedicle, which would account for her previous slight attacks. But even though the torsion was found at the operation to be complete and the cyst and Fallopian tube almost gangrenous, there were none of the usual symptoms and signs of an acute abdomen.

## Reports of Societies.

### PERFORATION OF GASTRIC AND DUODENAL ULCERS.

A HUNTERIAN Lecture was delivered at the Mansion House on January 19th by Mr. G. GREY TURNER (Newcastle-upon-Tyne), who took for his subject "The perforation of gastric and duodenal ulcers." Mr. H. W. CANSON, President of the Hunterian Society, was in the chair.

Mr. Grey Turner, whose lecture was accompanied by many tables of statistics, said that since 1901 he had had to do with 194 cases of perforation, but these included some cases of localized perforation, incomplete operations, and cases in which it was eventually decided not to operate. Eliminating these, and confining himself to general perforations in which he performed a complete operation, he was left with 147 cases. These cases had resulted in 124 recoveries and 23 deaths, the percentage of deaths being 15.64. But if only those cases were taken which had been operated on within twelve hours of perforation, the death rate was reduced to 8.16 per cent. The actual figures were: perforated gastric ulcers operated upon within twelve hours, 27, with 3 deaths; perforated duodenal ulcers, 71, with 5 deaths. Thus a very essential point in the treatment of this condition was early diagnosis. If a case were taken in hand reasonably early and carried to a successful issue, the credit lay with the general practitioner who had detected the condition and advised the operation, rather than with the surgeon who had actually carried it out. He was sure that there was no new refinement of operative technique which had anything like the value of a reduction in the period elapsing between perforation and operative interference. Of his 194 cases, 147 were males and 47 were females. With regard to age, it had rather surprised him to find how many of the patients were over 50—namely,

6 gastric cases and 40 duodenal. The fact, therefore, that symptoms occurred in a comparatively elderly person need not deter the making of such a diagnosis. He wished also to emphasize the frequency of acuteness in the ulcer which perforated. The perforation which occurred was often that of a second contact or "kissing" ulcer on the opposite wall of the stomach to that of the chronic ulcer. He was convinced that there was an acute ulcer whose principal characteristic it was to perforate. With regard to the after-history of the 120 recovered cases which could be traced, 61 were quite well, 19 had slight digestive trouble, 18 had had to undergo a further operation, 2 had died from some sequel of the original trouble and 9 from other causes without recurrence, and 3 were known to be well shortly after the operation and were then cured, he thought that the choice of surgical procedure, he thought that the first duty of the surgeon was to save the life of the patient, and in this connexion his figures with regard to immediate gastro-enterostomy suggested that this resort added to the mortality. He had done primary gastro-enterostomy in 26 cases, with 20 recoveries and 6 deaths, and of the 98 cases without primary gastro-enterostomy 81 had been recoveries and there were 17 deaths. He was of opinion that the best thing to do was to get the patient over the calamity of perforation, and then, if it was evident that a gastro-enterostomy was necessary for the cure of the trouble, to perform this as a delayed operation before the patient left the hospital. He had done such a delayed operation in 11 cases, and there had been no deaths. The average hours of perforation in these cases had been nine, and the longest interval between perforation and gastro-enterostomy spoke with enthusiasm of the value, in had cases of general perforation, of a temporary gastrostomy. He had employed this measure 28 times, and there were 8 deaths, but, although this death rate of 30 per cent. was a high one, it had to be remembered that the average number of hours of perforation in these cases was seventeen. In 22 operations and both patients died. Nevertheless, he felt that this procedure in many cases had been of the greatest possible help. With regard to irrigation of the peritoneum, he had lost his early belief in this procedure, and he exhibited a table showing that in 117 cases irrigated there had been 19 deaths, and in 25 cases not irrigated 4 deaths; but while the percentage of deaths was much the same in both these categories, the average period of perforation in the cases irrigated was eleven and a half hours, and in the non-irrigated cases twenty-two hours. Also, out of 23 cases which developed gross complications, 20 had been irrigated—an incidence of 17 per cent. of irrigated cases. In operating he thought the surgeon should be content with the middle line of incision. Very often the stomach was distended, and in these circumstances great help would be found in passing a stomach tube while on the operating table, when the stomach would go down like a big balloon. With regard to complications, subdiaphragmatic abscess had occurred in 8 cases with 3 deaths, pneumonia and pleurisy in 7 cases with 2 deaths, pelvic abscess in 3 cases with 2 deaths, gastric fistula in 3 cases with 1 death, pulmonary embolism in 1 case which died, and prolapse of intestine in 1 case which recovered.

Mr. JAMES BENNY complimented Mr. Grey Turner on the way in which he had trained general practitioners in Newcastle to recognize gastric and duodenal perforations and send their patients without loss of time to the infirmary. He was of opinion that in the great majority of cases there was no need to drain at all; in a certain number it was well to put in a single drain, but it should be taken out next day. He also believed that irrigation should rarely be done. His own practice had been not to do gastro-enterostomy, which seemed to add a great deal to the risk of the operation.

Mr. JAMES SHERNEN said that twenty years ago the acute ulcer which perforated was met with much more frequently than now; the majority of cases which perforated nowadays seemed to be chronic, and to have given symptoms for many years. If the ulcer, whether of the stomach or the

duodenum, was a chronic ulcer, he thought that, in addition to closing the perforation, at some time a curative operation must be done. The choice of the time would depend on the experience of the surgeon and the condition of the patient.

Mr. R. P. ROWLANDS thought that if the operation of gastro-enterostomy became a routine a high and quite unjustifiable mortality would result; but in a few cases in which it was not possible to close the perforation a gastro-enterostomy might be the only life-saving measure.

Mr. GORUOX-TAYLOR agreed that the mortality of perforation of gastric and duodenal ulcer had been lowered, not by any particular modification of surgical technique, but by the comparatively early date at which, even in London, cases of perforation now came into the hands of the surgeon.

Mr. A. J. WALTON said that in his experience these ulcers were nearly always chronic. This was borne out by the history elicited in a very large proportion of the cases which had come under his observation, by the indurated edge of the ulcer, and by the findings at necropsy. He thought that in nearly every one of these perforated ulcers gastro-enterostomy should be done, but, he agreed, not always at the time of the operation.

Mr. T. P. LEGG was of opinion that, as a general rule, they should be content with suturing the ulcer without doing a gastro-enterostomy. Mr. W. E. TANNER referred to the wide distance it was necessary to go with the sutures beyond the perforation to get them to hold; this bore out the idea of chronicity.

Mr. GREY TURNER, in replying on the discussion, said that in certain cases gastro-enterostomy should undoubtedly be carried out at the primary operation, but he thought that the table of mortality would be lowered if it was generally agreed that whenever possible the operation should be left for a later occasion.

### PNEUMOCOCCAL PERITONITIS.

A JOINT meeting of the Sections of Children's Diseases and Surgery of the Royal Society of Medicine was held on January 23rd, with Dr. HUGH THURFIELD in the chair.

Dr. HECTOR C. CAMERON introduced a discussion on pneumococcal peritonitis. While the incidence of this disease fell very largely amongst girls of 5 to 15 years of age, it was overstating the case to say, as some authorities had said, that it was confined to the female sex, since he had seen three cases amongst boys. In early infancy this disproportion was much less marked, and the two sexes were almost equally, though comparatively rarely, attacked. As regards symptoms, there was often a prodromal period of some days, during which diarrhoea was very frequently present before severe abdominal pain and a rise in temperature announced the spread of infection to the peritoneum. This prodromal diarrhoea, though not invariably present, was a very valuable aid to diagnosis; two illustrative cases were cited. Primary pneumococcal peritonitis (the secondary form hardly came within the scope of the discussion, since the peritonitis was but a small part of generalized pneumococcal infection) had been divided into two types—a fulminating and a comparatively mild. Since it was possible to have every gradation between these two extremes, Dr. Cameron preferred to consider the disease rather as one exhibiting three phases—a stage of onset, a stage of high pneumococcal fever, and a stage in which the outstanding symptom was a residual collection of pus in the peritoneum (an "abdominal empyema"). The onset was generally sudden and marked by severe abdominal pain. Within three hours in one case a child exhibited delirium, with a temperature of 105° F. The patient rapidly became flushed and drowsy, and the abdomen distended. This child died a few days later after laparotomy had been performed. The dramatic suddenness of onset in such cases resembled that of perforation of a gastric or duodenal ulcer, with which they were happily unlikely to be confused owing to the rarity of the latter condition in childhood. Less severe cases, however, might resemble appendicitis, and were frequently diagnosed as such. If life was prolonged beyond this stage there followed a period of high fever, lasting two or three weeks or longer, during which there was com-

paratively little pain and few signs of abdominal disturbance. Dr. Cameron believed that this coincided with the exudation of fluid into the abdomen. During this phase the differential diagnosis had to be made from typhoid fever. Irregular intermission of the fever and high pulse later heralded the third phase, during which the patient began to be sensible of his surroundings. Finally, a localized abscess or abscesses formed, and recovery usually followed drainage. The abscess was generally in the pelvis or the subphrenic region, but was occasionally divided up into loculi spread irregularly over the abdomen. In one case six separate abscesses had formed at long intervals. In this stage the differential diagnosis lay between pneumococcal and tuberculous peritonitis, as the child was wasted and ill, and presented a distended abdomen with signs suggesting free fluid. Rarely there were latent forms in which the abscess had a tendency to evacuate itself through the bowel or bladder. In other cases the resemblance to tuberculous peritonitis was heightened by the pointing of the abscess at the umbilicus, but with the difference that the pneumococcal abscess burst with great rapidity, whereas the tuberculous abscess, as was well known, might appear to be on the point of evacuating for a long time before doing so. Dr. Cameron added that while there were occasional cases which ran an unusual course this description would fit the majority of cases. The treatment of cases of pneumococcal peritonitis in the "abdominal empyema" stage was obvious—such cases should be drained, and almost invariably did well. But the question of operation during the early stage was not an easy one to answer, and resolved itself into the question of whether or no drainage helped the patient in any way in antibody production. His own experience was that a fall in temperature only rarely occurred after drainage in the acute stage, and that further operation for residual abscess was generally called for. He had therefore come to the conclusion that it was better not to operate until there was a definite localized abscess, but to keep up the patient's strength until that time by every possible means. He applied ice to the abdomen and exhibited opium, and in some cases antipneumococcal serum. Fraser had had considerable success with blood transfusion in these cases, but the speaker had no personal experience of this. This expectant form of treatment must naturally only be employed where the diagnosis of pneumococcal peritonitis was clear; if there was any doubt as to whether the case was one of fulminating appendicitis operation should be performed at once.

Mr. GEORGE WARREN said that pneumococcal peritonitis belonged to the very small group of diseases which could be diagnosed, at least at a certain stage, with confidence by the clinician without submitting any material to pathological investigation. This form of peritonitis presented the paradox that all the ordinary signs of inflammation of the peritoneum were strikingly and characteristically absent, for within a few hours of the onset pain had disappeared and no tenderness, muscular rigidity, or immobility of the abdominal wall could be elicited. Further, except for slight diarrhoea and vomiting at the outset, the normal functions of the bowel remained unimpaired throughout the course of the illness; even the appetite was good so long as it was not interfered with by excessive pyrexia. The only evidences of persistent inflammation were the swinging temperature and accelerated pulse. This remarkable absence of symptoms had its parallel in the inflammations due to the pneumococci in all parts other than the lungs and pleurae, for pneumococcal otitis media, pericarditis, arthritis, etc., were all painless within a few hours of the onset. The only positive sign of involvement of the peritoneum was a steadily increasing tumescence of the abdomen first seen in the subcostal grooves, the groins, or the region of the umbilicus. This swelling was due to the outpouring of the green non-irritating pus and not to distension of the gut. As an illustration the case of a baby girl, aged 14 months, was quoted. The child had had a feverish illness of six days' duration which began with sharp but transient pain in the left iliac fossa, with vomiting and diarrhoea for a few hours only. On examination the left side of the abdomen and pelvis, as high as the iliac crest, was found to be full of fluid. As the child had a vaginal discharge he hazarded the conjecture that

the pneumococcal infection diagnosed had spread from the left tube. At the operation the usual large collection of greenish pus was opened, and the left tube, which oozed pus through a patent abdominal ostium, was removed. This child made an uneventful recovery. Another case, in which after operation for empyema the significance of slight abdominal symptoms and tumescence was overlooked, died; post mortem the abdomen was found to contain a large quantity of pneumococcal pus, drainage of which would probably have saved the patient. After contrasting the progressive toxæmia and absence of signs of peritonitis which occurred in the pneumococcal form with the striking symptoms and absence of toxæmia which so often characterized tuberculous peritonitis, Mr. Waugh proceeded to the discussion of treatment. Some cases recovered without a diagnosis having been made and without any specific form of treatment. Evidence of this was found in a number of cases who first presented themselves with an encephalitic abscess in the abdomen. Treatment in the residual stage was standardized and consisted of simple drainage. Treatment during the invasion stage presented the difficulty that the clinical syndrome was sometimes indistinguishable from that of an acute inflammation of an appendix "concealed" beneath the liver, behind the root of the mesentery, or in the pelvis. In such cases immediate operation should be undertaken. When the abdomen was opened the pathological appearances of early pneumococcal peritonitis were unmistakable: a little free fluid, always cloudy and frequently containing a few flakes of lymph, was present, and over a wide area the coils of small intestine were an angry red with their lustre somewhat impaired. Similar changes to an equal or less degree were exhibited by the appendix. In such cases he removed the appendix if involved and drained the abdomen. The latter was essential, for in two cases of early pneumococcal peritonitis in which the appendix had been removed, and the abdomen closed without the condition being recognized, the patient was only saved from disaster by a subsequent reopening of the abdomen and liberation of quantities of characteristic green pus. It was difficult to understand why drainage should be helpful, but it was his impression that it was so. He had never seen a fatal case in which operation was done within thirty hours of onset, whilst many cases of concealed appendix had been discovered. Finally, in the intermediate stage, the need for operation was determined by the degree of toxæmia and its tendency to increase. A climbing pulse rate was an indication for operation, but if the pulse rate remained fairly constant in spite of a swinging temperature, operation might be safely deferred. In some cases the illness came to an abrupt end about the tenth or twelfth day and any fluid in the abdomen was absorbed. Presumably in these cases the pneumococcus was entirely killed, for in the residual cases, which came to operation many months after the original illness, the pneumococcus could always be cultured from the pus. Mr. Waugh considered that the sinister reputation of pneumococcal peritonitis was undeserved; it probably arose from confusion between the primary type of case and pneumococcal septicaemia in which involvement of the peritoneum was but a small part.
